JANUARY, 1912 TO DECEMBER, 1912, INCLUSIVE

BOWLING GREEN, KENTUCKY

1913

INDEX TO VOLUME

CONTRIBUTORS.

- Abell, Irvin, 81, 437, 623, 639, 660, 868.
 Abell, N. D., 252, 722.
 Acton, J. W., 414, 456, 596, 685.
 Adams, J. J., 600.
 Albright, G. H., 47.
 Allen, E. S., 60, 84, 534, 536, 614, 650, 731, 855, 862, 809, 817, 819, 821.
 Allen, F. L., 509.
 Allen, M. K., 168.
 Allen, Oscar, 332, 511.
 Amon, J. A., 509.
 Anderson, D. B., 237, 457.
 Anderson, W. W., 15, 19, 36, 139, 289.
 Arnold, W. F., 186, 241, 242.
 Ashbury, W. F., 509.
 Akenstedt, F. C., 61, 70, 261, 650, 653, 808, 863, 910.
 Asman, Bernard, 59, 146, 361, 362, 444, 613, 627, 801.
 Atchison, W. A., 91.
 Atkinson, J. L., 423, 716, 802.
 Auld, C. Z., 145, 800.
- Bailey, E. R., 332.
 Bailey, Steele, 686.
 Baldauf, Leon K., 909.
 Ballard, J. J., 242.
 Baltzer, L. P., 45.
 Bandy, F. C., 597.
 Barbour, Philip F., 100, 467, 737, 738, 902.
 Barker, J. H., 327.
 Barkley, Arch., 708, 406.
 Barnett, W. T., 633.
 Barrow, Woolfolk, 800.
 Barrieth, Walter, 46.
 Bassett, W. M., 250.
 Bates, R. A., 145.
 Bates, S. W., 416.
 Baxter, A. A., 422.
 Bell, Maurice, 482, 509.
 Bizot, A. R., 359.
 Blair, J. M., 457.
 Blackburn, J. H., 241.
 Blackman, W. S., 685.
 Blackerby, R. N., 633.
 Bloch, Leo, 538.
 Bloch, O. E., 648.
 Blythe, Vernon, 21, 125.
 Board, Milton, 69, 266, 570, 657, 927.
 Boggess, W. F., 33, 84, 252, 265, 353, 613, 749, 800.
 Bolling, W. A., 852.
 Bots, A. T., 233, 415, 564, 599.
 Bowling, W. W., 600.
 Bowen, D. C., 279.
 Bradley, E. B., 499.
 Branson, E., 37, 238.
 Brasseur, J. B., 218.
 Bremerman, Lewis, 109.
 Brennan, J. O. A., 646, 647, 860, 869.
 Briggs, W. A., 241, 852.
 Britt, W. T., 599, 683.
 Brock, C. W. P., 236.
 Brock, O. D., 239.
 Brunner, Herbert, 71, 145, 648, 649, 860, 868, 872, 342, 443, 536.
 Brodeur, C. K., 456.
 Brown, E. J., 422, 507.
 Brown, J. A., 800.
 Browne, J. H., 658.
 Brown, O. W., 633.
 Bruce, E. T., 646, 731.
 Bruner, W. T., 444, 644, 645, 658, 659.
 Bryant, J. F., 327.
 Buchanan, C. B., 414.
 Buntin, E. T., 332.
 Burrow, R. C., 46.
 Byrne, Walter, 704.
- Cain, A. W., 147.
 Caldwell, J. A., 47, 750.
 Carpenter, J. G., 8, 21, 135, 140, 143, 914.
 Carroll, Owen, 238, 418.
 Carter, J. L., 418.
 Cartwright, P. D., 233, 512, 750.
 Cartwright, H. P., 241, 750.
 Casper, M., 662, 746.
 Caudle, B. A., 596.

COUNTY SOCIETY REPORTS

Campbell-Kenton—The regular monthly meeting of the Campbell-Kenton County Medical Society was held on the evening of September 19, 1912, with the President, J. G. Furnish, in the chair.

The minutes of the previous meeting were read and approved.

CASE REPORTS:

X-ray plate of "Hour-Glass Stomach," was shown by **Dr. Rankin**.

On motion, made and carried, Drs. Rockhill and Dunham, of Cincinnati, Ohio, were given the privilege of the floor.

Application of C. N. Heisel was read and on motion, made and carried, the rules were suspended and a ballot ordered spread. Dr. Heisel was unanimously elected to membership.

J. R. Meek extended to the Society the use of the Anti-Tuberculosis League quarters as a meeting place.

W. G. Brown read a paper on "Relative Value of Early Tests for Tuberculosis." Discussed by Drs. Rockhill, Dunham, Meek, Nelson, Anderson, Rankin, McCullum, Furnish, George Herman, and Jos. Back.

Number of members present, twenty-eight.

Adjourned to meet October 17, 1912.

J. A. RYAN, Secretary.

Campbell-Kenton—The monthly meeting of the Campbell-Kenton County Medical Society was held on October 17, 1912, with J. G. Furnish in the chair.

The minutes of the previous meeting were read and approved.

Application of C. A. Sutton, by demit from Pastatune-Camden-Dave County Medical Society of North Carolina, was received. Dr. Sutton was admitted to membership.

Application of R. G. Boehm was referred to the Board of Censors.

A motion by Dr. Merriam, that the present Program Committee be reappointed for the ensuing year was carried.

Moved and carried that the Publicity Committee, if they deem it feasible, make arrangements to entertain speakers from the "Speakers' Bureau" as outlined by the A. M. A.

J. A. Hohnstedt read a paper on "What is Rheumatism," Discussion by Drs. Newman, Caldwell, Brown and Bonar.

There were twenty-four members present.

Adjourned to meet November 21, 1912.

J. A. RYAN, Secretary.

THE NEW YEAR.

The New Year opens up with the Kentucky State Medical Association in better position in every way than it has ever been. The medical profession of Kentucky has never been more active and has never accomplished as much as a profession as it did last year. In every county our societies have been active in the education of the public as to the prevention of diseases and as to the dangers of worthless classes of patent medicine. The new Bureau of Vital Statistics has received the practically unanimous support of the doctors of the State. Few other states have accomplished as much in ten years in this work as has been accomplished in Kentucky in one. It will be a revelation to most of us that 17 per cent. of all deaths in our Commonwealth are due to tuberculosis in some one of its forms, and that 41 per cent. of the total number of deaths have been due to preventable diseases. Equally striking, is the report of 947 deaths from typhoid fever and 463 from diphtheria or membranous croup. The people must be educated as to the meaning of 392 deaths from measles and 338 from whooping cough, which are ordinarily considered by them as the harmless diseases of childhood. All of the above figures are for the first eleven months of the new law. It is rather encouraging that during this period that while 27,956 deaths have been recorded, that 55,307 births, including still births from both figures, are on file. There is no question but that Dr. Heizer's Bureau has made good, that its value to the profession and to the people in promoting longer life and better health will soon be appreciated by everybody, and that the lessons of this year emphasize the importance of every doctor in Kentucky making more careful diagnosis,

keeping more careful records, and being even more attentive to the details and promptitude, which are necessary to making the Kentucky Bureau of Vital Statistics better than in any other state.

The same record of successful accomplishment is due the Bureau of Bacteriology. Dr. South has examined and reported more than seven times as many specimens as have been examined by any other state laboratory in the first year of its existence. One-third of the doctors of the State have sent in specimens and more than fifty of the most active practitioners in Kentucky are sending from three to twelve specimens a week. All this is being done without a penny's cost to the profession and it is, of course, most helpful to the sick people of the State.

The Bureau of Sanitary Engineering has accomplished a great deal in the preliminary survey of the public water supply of the State. Under the active management of Prof. E. H. Mark, the water laboratory is now in active operation and specimens are being examined daily from all over the State. It is especially urged that physicians and others desiring sanitary water analysis, write for the laboratory containers and instructions as to how to obtain samples. It is, also, to be remembered that industrial analyses are not made in the laboratory of the Board for obvious reasons.

A thorough survey as to the prevalence of hookworm has been begun. Dr. South has found the disease to be in existence in 21 counties. These counties are typical of all the others as to health conditions. To succeed in making such a survey of real value, the co-operation of every physician in the State is required. Our Council has about decided to ask every doctor to select ten children in his environment, who go barefooted a greater part of the year, whose home have no

privies, and who looks anaemic or pot-bellied and stunted, and obtain specimens of feces for examination in the laboratory. As soon as this has been done, we will be able to begin the active work of education necessary to teaching the people, themselves, not only how to prevent this but most of the other preventable diseases.

The especial congratulations of the Association are to be extended to our Medico-Legal Committee for its effective work in checking blackmailing during the year. Every unjust suit brought against our members has been successfully defended without cost to them. Many similar suits have been prevented, and in a very small number of instances where doctors have been obviously at fault, they have been kindly but firmly so advised as to enable them to make the best of a bad situation.

THE JOURNAL, itself, has a larger circulation and the largest income it has ever had. It is known to our physicians that every cent of its income is spent in printing a bigger and better JOURNAL. To this end, several improvements are proposed for the New Year. It is proposed to conduct a department, telling about the progress of reform in therapeutics that will help our physicians in a unanimous determination to get rid of the dishonest patent and proprietary medicine industry, as far as it is a burden to our sick people. In addition to this, we propose in conducting a news department which can only be made successful by the active cooperation of every reader. We want to know every thing of interest to the doctors in every county, news of epidemics, hospitals, interesting cases, marriages, births and deaths, public movements and everything else which concerns the doctor not only, individually, but as a citizen and a leader in his community, will be received and published. This department will be under the active charge of Miss Clyde Howell in the JOURNAL office of Bowling Green, and she will welcome suggestions and news items from every doctor in Kentucky. It is especially urged that clippings of general interest from local people be sent in. What the JOURNAL desires to do is to keep every other county familiar with what is going on in your county.

It is of the utmost importance that every member recall the fact that his county and state dues should be paid in to-day. Remember that your county secretary has his own work to do, and that you are not eligible for defense in the Medico-Legal Committee unless you are in good standing with your dues fully paid up.

THE REFORM IN PROPRIETARY MEDICINES.

Ever since the American Medical Association's Council on Pharmacy and Chemistry was organized, this JOURNAL and the Kentucky State Medical Association have been consistent champions of the American Medical Association's propaganda for reform in proprietary medicines. In furtherance of this work we have given considerable space to the reports of the Council on Pharmacy and Chemistry and this without caring in the least that such publications aroused the resentment of firms that had reason to shirk publicity.

All, or nearly all, the remedies that are on the market have been investigated by the Council and those found worthy of the physician's confidence are included in the book, "New and Nonofficial Remedies" and which should be in the library of every physician since it can be obtained for the cost of printing by writing the American Medical Association, 535 Dearborn Avenue, Chicago, and every physician can and should be posted in regard to reliable proprietary remedies. Inasmuch, however, as new remedies are constantly coming out and being investigated, it is proposed to establish a department where these may be discussed. This department is to be known as "The Truth about Medicines" and it will contain under "Reliable Medicines" brief descriptions of new substances which the Council examines and finds eligible for inclusion with New and Nonofficial Remedies. Under the head of "Reform in Medicines" we shall present general information in regard to the composition, quality and value of remedies of all kinds—particularly the nostrums and humbugs which are shown up in the reports of the Council on Pharmacy and Chemistry and the A. M. A. Chemical Laboratory.

In order that they may actively aid in the great reform tending towards rational therapeutics, our readers should give careful consideration to the facts brought out in this department. Correspondence with the Laboratory in Chicago is invited by members interested in this Department.

IN DEPREICATION OF THE NEGLECT IN GENERAL BY PHYSICIANS OF THE MEDICINAL TREATMENT OF DISEASE.

INTRODUCTORY.

This thesis assumes at the outset that the element of the medical profession that fancies itself ultra-progressive, is prejudiced against almost all of the empiric galenicals; that its tone is consistently pessimistic as regard prognoses as influenced by treatment in individual cases; and that it approves only of the neo-oogle

scientific remedies—and of these but mildly.

The grounds for this assumption must necessarily be comprised in the writer's experience and in his observations. They are, in brief: (1) The approving statement of an esteemed colleague that he has spent two weeks busily observing the methods of a first-class hospital on the Atlantic seaboard that maintains 600 beds without having known of half a dozen remedies having been prescribed; (2) The keenness that the graduates of the best American medical colleges almost invariably show in collecting and in reporting rare conditions and anomalies that more than often do not involve actual diseased condition nor interfere much, if at all, with the health of those exhibiting them in their persons, and the frank avowals of preference by the graduates aforesaid for such employment. (These expressions of preference are often coupled with confessions of distinct disgust for the routine work of general practice.) (3) The admissions that are current on every hand of the decline of the art of prescribing, thanks mostly to the unexaggerable politeness and complaisance of the "manufacturing" pharmacists, and the small recognition and support accorded to the real pharmacist, who seems destined not only eventually but even soon to be degraded into the manager of a soft-drink saloon; and (4) The unsatisfactory state of the sections devoted to the treatment of disease in every standard text-book without exception with which the writer has any comfortable familiarity.

The cognate branch of practice—*materia medica*—has fared but little better; for it cannot be denied that America has not yet produced anyone that has yet done for her budding medical sons what J. Mitchell Bruce did for his contemporaries and for some of their successors.

It seems distinctly an American habit to seek for some one to blame upon recognizing an untoward condition or tendency, and to stop with pointing out the unlucky victim for the occasion. If, haply, he be punished, not only is the penalty disproportionate and erratic; it may also obviate its own desired effects. It rarely, if ever, improves the avowed abuse.

It would be absurd to undertake to correct within the limits of a volume, such abuses as this writing states as prevailing, much the less of an editorial page. This writer hopes only to evince his entire earnestness in the matter, and to induce introspectiveness into the bosoms of a few in whose attention he rejoices. He rejects altogether the implication that whoever points out a grave fault must produce forthwith a specific remedy for it; because, if everyone but a philosopher were to be excluded from the province of induction,

criticism would languish and very soon perish, and progress would become impossible.

His limited acquaintance with, and his small practice of, the Christian faith has led him nevertheless to believe that the plan of redemption offered by Jesus Christ a scant score of centuries ago, comprised merely each person's improving *one person* and, of course, beginning upon himself. He denies any imputation of sacrilege in this connection; for if there be any person whomsoever that enjoys boundless opportunities for dispensing Christlike aids, comforts and benefits, surely that person is The Good Physician. It should matter little to such a real man that current practices in the Christian sects have apparently debased Christ's ideal almost completely into creeds and dogmas that permit their adherents to do about as they please and to try to make others do as they do. This ideal of Christ's suggestion remains a workable and a working plan for all improvements of importance.

The first Hippocratic maxim and the Biblical advice not to weary in well-doing embrace all essential directions needed by any modern medical man in carrying out his work of self-improvement. However, lest the writer incur the reproach of mere wordy preachiness, he promises hereby to give in some future issues at length, as well and as fully as may be permitted, his experiences and his observations regarding the treatment of several important common diseases.

W. F. A.

THE INDEX.

This issue contains an index of the JOURNAL from January, 1911, to January, 1912, inclusive. Each original article is indexed according to the leading word of the subject and cross-indexed when the caption embraced more than one topic.

Special attention and space has been given to the reports of County Societies so that if a file of the JOURNAL is kept by each society these may be used as the official minutes and easily referred to by their officers.

We urge the secretary of each society to report as fully as possible all the discussions, so that these physicians' names may be added to our list of contributors.

The contributors consists of a list of those who have written original articles, editorials, used the columns of the Forum, or discussed subjects in the county society.

There is an alphabetical list of all our advertisers for the year, reference to their pages have been necessarily omitted, but an abbreviated title of the products they represent is given so that our readers can readily refer to them.

MEMBRANOUS CROUP.

Laryngeal diphtheria (membranous croup) is probably as terrible a condition as ever confronts a physician and its death rate even under the best management is appalling. The following points gleaned from practical experience should be of interest to every practitioner.

1. It is time to drop the old name membranous croup, which tends to obscure the true nature of the disease and call it what it is—laryngeal and tracheal diphtheria.

2. It should be treated as diphtheria and massive doses of antitoxin should be given as soon as the diagnosis is reasonably certain. Ten thousand units is not too much for the initial dose.

3. All children who have been exposed should be immunized with 1000 units each.

4. Quarantine should be strictly observed.

5. While using all possible means to facilitate the expulsion of the loosening membrane, watch the chest and lips to keep accurate track of the amount of dyspnoea. If the lips become blue, the face pallid and if the sternum sinks far in with each effort of respiration, intubation or tracheotomy must be done at once.

Now which of these operations offers the patient the best chance of recovery?

Theoretically the answer is intubation, but practically I believe in tracheotomy for the following reasons:

1. Tracheotomy is done in the open where every move can be carefully observed. One can do just what one starts to do.

2. What little breathing space the child has is preserved intact till the tracheal tube is in place. In doing an intubation the child is frequently killed by suffocation in the clumsy efforts to introduce a tube which you cannot see into a hole which you cannot feel.

3. The tracheotomy tube is double and if it is blocked with membrane the inner tube can be easily removed by the nurse, cleaned and reinserted with no discomfort to the patient. If an intubation tube suddenly blocks up the child may die before relief can come.

4. When the membrane extends, as it frequently does, down into the trachea and bronchi, the tube may be easily removed, the child placed in tracheotomy position and with the aid of a common lamp and head mirror the trachea can be swabbed clean clear down to its bifurcation. Furthermore, glycothymoline or some other alkaline wash can be easily applied to the tracheal mucous membrane keeping the surface moist and clean.

5. The removal of an intubation tube is a difficult feat. Let anyone who doesn't believe this try it.

6. After the intubation tube is taken out it must often be re-introduced because of oedema or spasm of the larynx. I saw one case die in the nurse's arms while the doctor was vainly trying to re-introduce the tube. When a fenestrated outer tracheal tube is used one can test the condition of the larynx by simply putting the finger over the mouth of the tube and seeing whether the child can breathe freely through the mouth. The tracheal tube may be removed and replaced at will by the nurse with no danger whatever.

Now a few practical points about the operation.

1. The patient is placed on his back with head hanging over the edge of the bed. One nurse holds the baby while a second assists the doctor.

2. Very little anaesthesia is necessary. A few whiffs of chloroform only should be used after which a thorough infiltration of the tissues with 1-20 of one per cent cocaine.

3. Use a knife for the incision through skin and subcutaneous fat and then put it to one side.

4. The further dissection should be done with scissors having points like artery forceps which are very narrow but blunt so that they cannot puncture any vessel or do any other damage. If they are curved on the flat they are more convenient. This is a very fine method of dissection not only in this operation but in many others. In all the books describing tracheotomy we find the statement that the bleeding is the most troublesome thing. There really need be no bleeding. The muscles may be grasped by two artery forceps just as is done with the peritoneum in opening the abdominal cavity. These are lifted up and away from each other, the blunt scissors are pushed into the tissue between them, opened and pulled out. This tears the tissues longitudinally but causes no bleeding. Each layer is separated in the same way till the trachea is reached which need not consume 40 seconds in time.

5. A sharp tenaculum is hooked under the cricoid cartilage and the trachea thus brought well up in sight.

6. With a sharp knife a longitudinal slit is made in the trachea large enough to admit the tube.

7. With a short curved round needle a stout silk ligature is passed through each lip of the tracheal wound. Both ends of these ligatures are left hanging out of the wound on each side.

8. By pulling apart these ligatures the wound may be opened and the tube inserted and taken out at pleasure with very little disturbance to the patient. These ligatures are

left in place till the tube is permanently removed when they may be easily pulled out.

9. A nurse should be in constant attendance till the case is well. R. H. C.

A NEW EDITOR.

It is with considerable interest that we note the selection of Dr. Charles E. deM. Sajous, as Supervising Editor of the New York Medical Journal. We trust that under this new management the scientific excellence of the Journal will be continued, and that Dr. Charles E. deM. Sajous will be able to persuade the Elliott Publishing Company, who owns it, to bring its advertising pages up to a fair degree of honesty.

SCIENTIFIC EDITORIALS.

TONSILLECTOMY OR TONSILLOTOMY?

Having seen in consultation in the past few months, a number of the after affects of tonsillectomy, I am inclined to believe the Surgical pendulum has swung too far, and instead of radical conservatism we have reached radical radicalism.

The difference in the opinions of a large number of rhino-laryngologists is due to the uncertainty of our knowledge of the function of the gland. My own views, as expressed in the discussion of this subject at the last meeting of the A. M. A., in Chicago, has not changed. Because of the larger number of operators doing tonsillectomy and of the prominence of the necessity for relief from diseased adenoid and tonsils, on account of their causing rheumatism and other serious lesions in the body, leads me to ask with Joseph A. White, "is the present holocaust of tonsils necessary? Is there not too great a tendency to radicalism? And is there not a happy medium between the terrible onslaught of tonsils and a conservatism of neglected operative procedures which are really necessary and safer, hence the better plan?" Some of the sequelae above referred to which I have seen where the pillars of the soft palate were out of alignment due to cicatricial contraction causing tension and interference of palate movements, making swallowing a discomfort. As one child 14 years of age expressed it, "I do not swallow as good on one side as I do on the other." The anterior and posterior pillars were matted down by adhesions causing the traction to be so great around the fossa of Rosenmuller as to cause a partial closure of the eustachian tube with subsequent tinnitus. The great traction made with the tonsillar forceps which is necessary in some of the cases of submerged tonsils in order to pull them out so as to make a dissect-

ion, causes stretching of the tensor palati and levator palati group of muscles which cause loss of their tonicity, which results in the regurgitation of fluids through the nares. Five or ten years ago, I did tonsillectomy almost exclusively but in the last three or four years, except in selected cases, I do not dissect out the whole gland for reasons already published in several of my discussions. I see no justification of tonsillectomy as a routine practice in our surgical field. To sacrifice healthy tonsillar structures militates against an operator as a conservative surgeon, which is the first duty we owe our patients. The tonsils have efferent and afferent lymph channels which excrete and secrete elements that serve as a protectorate over the nature. Of this I am firmly convinced by clinical observation and this two-fold tonsillar function should be appreciated by the specialists more than the general practitioner. To prevent the intake and the output of deleterious elements should appeal to every student of physiology. "If we believe in the functional co-ordination of the glands with internal secretion, we must admit a compensatory ability and co-relation hypertrophy, for functional accommodation."—(Junus Glover). If this is true, why should we remove the first barricade or outer guard causing the deep structures of the inner guard to work at a risk of graver infection? Diseased tonsils cause serious systemic disturbance in two ways: first, when they are so large they produce a mechanical obstruction; second, when they are *phymosed*; by this I mean submerged with adhesions to the pillars, causing a retention of the natural secretion and the formation of caseous masses remaining for so long a time that these become purulent, and a slow sepsis is the result. The phymosed, adherent tonsils do far more injury than the large protruding ones. In the latter instance, the act of deglutition squeezes the retained secretion out of the crypts, thus draining them. Tonsillitis is usually a local manifestation of a constitutional or systemic disturbance. I do not believe that any cases of acute follicular tonsillitis are relieved without the use of systemic medication, and why should the tonsil which is a little enlarged and has a few follicles obstructed with cheesy masses in the crypts, be condemned to enucleation? Does the general surgeon excise lymph nodes in adenitis? On the contrary, he drains them. Does the gastronomic specialist snip off any portion of the buccal cavity in aphthous stomatitis? Does the dermatologist cut away any of the dermoid layer in the eruptive stage when the eruption is due to constitutional causes? These are somewhat parallel pictures to the tonsillar function.

The tonsil ranks in clinical importance with the appendix. Both appear to be insign-

nificant organs but to them more attention is drawn than to all the other organs put together. The function of both is still in obscurity and it is still the belief of many that we can get along without them as well as with them. It has been disputed by Mosher and others that the tonsil is a pathological formation, on the contrary he claims it is as much a part of the human organization as the thymus or thyroid gland, whatever its function may be. It is composed of tonsillar tissue and adenoid cells forming follicles and crypts which favor absorption and secretion. These layers of tissue are surrounded by a dense capsule of connecting tissue over which prolongations extend into the tonsil, dividing it into pockets or crypts. The gland lying between the anterior and posterior pillars of the palate united by mucous membrane attachments which are often mistaken for pathological adhesions, altho these attachments are often increased by repeated attacks of inflammation. These crypts are lined with stratified epithelium which are thicker than the surface membrane. I am in accord with the claim made that the gland acts as a barrier to the entrance of micro-organisms into the body, that it assists in leucocytosis, and produces phagocytes. In other words, "the healthy tonsil is a protective organ against infection and tho the crypts may be swarming with bacteria these stimulate its epithelial cells to throw out a ferment which in turn destroys the micro-organisms, a process known as bacterio-lysis"—(Wright). Often these cells lost their tone by pathological changes, local or constitutional, the process of bacterio-lysis is arrested and an infection takes place. I believe also that the function of the tonsil is to act as an eliminating organ for the toxins in the system. And being the point of least resistance, the infection is often first manifested there. That the tonsil in a diseased condition is a menace to the organism and is a focus of infection, has been demonstrated by an accumulated mass of evidence by observers, all over the world.

There are two routes of infection to the general system through the tonsils. One by way of the blood vessels and the other by way of the lymphatics. Bacteria pass along the lymph channels but do not penetrate the vessel walls, while the toxins do so, easily. Hence toxic infection of the system through the blood vessels, is much more common than the slower process of the lymphatic infection or bacteremia. An example of this is the rapid systemic symptoms of acute tonsillitis, whilst glandular enlargement at the angle of the jaw or cervical glands is rarely ever present at the beginning of an attack, and often not at all.

After many clinical tests and close observa-

tions on several hundred cases in the past 3 or four years, I am convinced that if the upper 1-3 or 1-2 of the tonsil is removed, the supar-tonsillar fossa made free, adhesions of the pillars prevented, this is all that is necessary. The lower 1-3 or 1-2 of the tonsil is left to perform its function, if it has one, and to preserve the acoustic properties of the pharynx, and whatever other function intended by nature. This lower portion being devoid of follicles and crypts, retains no secretions, and I have never known it to be primarily infected or to become diseased after the upper portion of the tonsil had been removed. Adenoid tissue should be thoroughly removed whenever it exists, care being taken not to use too much force with curette or forceps.

CONCLUSION.

When tonsillectomy is necessary, as it sometimes is, it must be made clear to the patient, or to the parents and friends, that it ranks with the major surgical operations and should be done in a hospital, with the same careful technique that any other major surgical operation is done.

Since the presence of diseased tonsils and adenoids in children is one of the greatest drawbacks to mental and physical development and a menace to health, and since so many serious complications and sequelae are being reported as the result of the radical operation of tonsillectomy, this word of caution does not seem out of place, because of the danger of bringing into disrepute one of the most important operations in surgery. As I stated at the meeting of the Mississippi Valley Association at Nashville, November, 1903, in the South this operation is one of the most unappreciated, underestimated and underpaid, of all surgical operations. This condition is largely due to the fact of the teachings and practices of years ago.

J. A. STUCKY.

Glaucoma.—Bjerrum presents evidence to sustain the assumption that glaucoma is not exclusively merely exaggerated intra-ocular pressure but that an irritative process is involved besides. This irritation seems to affect essentially the ciliary body. Excessive secretion follows, and this hypersecretion is the cause of excessive intra-ocular pressure. The primary irritation is probably of a toxic nature. He cites some typical cases to show this connection and the lesions encountered.

Generally speaking, functional kidney tests are of largest value in surgical diseases of this organ, although in chronic interstitial nephritis they have been shown to demonstrate the activity of urinary function.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form facts about the composition, quality and value of medicines. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A. Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and the Chemical Laboratory.*

RELIABLE MEDICINES.

Articles found eligible by the Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." **Crurin Purum** is quinin-bismuth sulphocyanate. It is an insoluble, inodorous powder. Used topically as an antiseptic. Mixed with an equal weight of starch, it is sold as Crurin Dusting Powder and is claimed to be of value as an application to leg ulcers. Kalle & Co., Inc., New York.—(J. A. M. A., Dec. 2, 1911, p. 1838).

Ciose is a water soluble beef protein containing 83 to 85 per cent. actual protein. Ciose is designed to augment the protein of any desired diet. Fairchild Bros., & Foster, New York.—(J. A. M. A., Dec. 2, 1911, p. 1838).

Enemose is a liquid containing nitrogenous substances from beef and wheat, carbohydrates from wheat and phosphate in a nonecquable, diffusible and assimilable form. It is designed for colonic alimentation. Fairchild Bros., & Foster, New York.—(J. A. M. A., Dec. 23, 1911, p. 2083).

Digalen Tablets contain 1-2 cc. (8 minims) digalen each. Digalen is described in "N. N. R., 1911." Hoffmann-LaRoche Chemical Works, New York.—(J. A. M. A., Dec. 23, 1911, p. 2083).

REFORM IN MEDICINE.

Sulphume, a nostrum sold by the Sulphume Company, Boston, Mass., is, according to a report of the A. M. A. Chemical Laboratory, a solution of calcium sulphid such as is obtained when sulphur, lime and water are boiled together. The solution is a rich golden yellow and has the disgusting odor of hydrogen sulphid. Its favorable reception as a "patent medicine" appears to depend on the old idea that anything that is nasty in taste or odor must be "powerfully good medicine."—(J. A. M. A., Dec. 2, 1911, p. 1853).

Tiz, exploited by Walter Luther Dodge & Co., Chicago, was analyzed by the A. M. A. Chemical Laboratory and found to consist of tablets which contain as essential constituents, alum, tannic

acid and salicylic acid. The tablets, dissolved in water, are said to "be good for sore feet." The usual exaggerated and unwarranted claims are made for this well-known astringent combination of doubtful value.—(J. A. M. A., Dec. 2, 1911, p. 1853).

Important Drugs. A committee of the Council on Pharmacy and Chemistry reports in regard to the compilation of a list of the more important and useful drugs. With a view of making materia medica instruction more efficient it is proposed that teachers and examiners limit their instruction to the more useful drugs.—(J. A. M. A., Dec. 9, 1911, p. 1930).

C. H. Carson, Quack. Some sworn testimony regarding the professional and educational qualifications of this quack are furnished.—(J. A. M. A., Dec. 9, 1911, p. 1930).

Medical Journals and the Great American Fraud. Leading members of the profession are contributors to medical journals whose advertising pages are full of pharmaceutical frauds and humbugs. Because of this support the profession is held responsible for the existence of proprietary frauds.—(J. A. M. A., Dec. 16, 1911, p. 2000).

The Alcohol Content of Elixirs. The needlessly high alcohol content of elixirs was discussed at a meeting of the Washington branch of the American Pharmaceutical Association. The branch regards with disfavor the continuance, in the National Formulary, of preparations that can be used as tipples.—(J. A. M. A., Dec. 16, 1911, p. 2013).

The DeBarthe Treatment for Rheumatism. This appears to be a side issue of the Neal Institute which exploits a "three day liquor cure." DeBarthe is not a physician. Still he appears to practice medicine and even to occasionally sign death certificates.—(J. A. M. A., Dec. 16, 1911, p. 2014).

Roentography with Kidney Calculi.—Areelin states that instantaneous exposures are liable to show up the stones much better than longer ones unless the kidney is completely immobilized. He insists further that the roentographer should always be present at the operation so that he can identify the stones by their shadows and see that none is overlooked. Areelin gives twenty-six different views of kidney stones to show the various sources of error.

Urine Reaction in Breast-Fed Infants.—Engle and Turnau state that a black precipitate forms in the urine of breast-fed infants when 15 or 20 drops of a 2 per cent. solution of silver nitrate are added to 5 c. c. of the urine. The discoloration reaches its height in ten minutes or still earlier if the fluid is heated. There is no black discoloration with urine from bottle-fed infants.

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

TRUTHS ABOUT THE OPTOMETRY BILL.

This bill grants to opticians (so-called "optometrists") the right to adjust lenses to people's eyes in need thereof, and denies them the right to use drugs. *Without the use of drugs, in certain cases, even the most competent physicians cannot properly adjust lenses to the eyes, especially in children and people under 35 years, and great harm can be produced by attempting such practice without the use of drugs.*

This bill is an invasion of the Practice of Medicine in one of its most important branches, and confers privileges on certain people untrained in medicine which in accordance with the wording of the act they are utterly incompetent to exercise.

The knowledge of optics alone, however extensive, does not render a person competent to do the work this Bill would give opticians the right to do.

To examine the eyes and adjust lenses one should have a knowledge of anatomy and physiology at least, but this Bill provides only a knowledge of optics.

The many diseased conditions of the body which may influence the eyes and vision are not considered at all.

The eye is an integral portion of the body, and is subject not only to diseases peculiar to itself, but frequently participates in, and gives evidence of, affections of the cerebro-spinal, cardiovascular, respiratory, renal and digestive systems, as well as those of the genital organs, the liver, accessory organs of nutrition or ductless glands, accessory nasal sinuses, blood, etc.

The ability to discriminate between visual defects due to diseases and those due solely to optical errors, both of which often exist at the same time, requires more ability than a simple knowledge of lenses.

Anyone who is unacquainted with this relationship and its effects evidently is unfitted to examine an eye for the purpose of correcting its defects, no matter whether this correction requires optical, surgical or medicinal therapeutics. He who is medically untrained is liable to fail to recognize, on the one hand, for example, glaucoma, or on the other, an albuminuric retinitis. In the first instance he endangers the patient's eyesight, in the second his life.

It is a most vicious type of special legislation in that it permits an Examining Board of five opticians to discriminate between opticians who apply for certificates of exemption. The recommendation of this Board is necessary before these certificates can be granted and this Board can limit its recom-

mendation to a chosen few, forming an optical trust.

It is the province of the optician to manufacture prescribed lenses and to attend to their mounting and suitable mechanical adjustment. It is not the province of the optician, nor that of any other person unprepared by medical education, to attempt to recognize diseases of or to prescribe lenses for, the human eye.

It therefore follows that a proper understanding of ocular therapeutics and the adaption of lenses for ocular disorders requires the skill of one who is medically trained in the best sense of that term.

Just as soon as refracting opticians receive state recognition by the passage of an Optometry Bill, they immediately assume and advertise equally with members of the medical profession, whereas they are not medically trained and the public is correspondingly deceived. This fact is well evidenced in an optician's circular at hand from which the following is quoted: "We are to-day approved and accepted as STANDARDS by special optometry laws in twenty-four States which now recognize the practice of optometry equally with that of medicine."

PRESIDENT'S ADDRESS

"UNITED WE STAND, DIVIDED WE FALL."*

By J. G. CARPENTER, Stanford.

Mr. President, Members of the Kentucky Medical Association, Ladies and Gentlemen, Loyal Kentuckians, American Patriots, Candidates for the Kingdom of Heaven, Welcome! Welcome! Welcome!

We are in "Our old Kentucky Home,"
The light shines across the hardwood floor,
more and more.

The hour of my execution has arrived. I have a few words to say. Let no man write my epitaph. As yet no man knows my motives, when I am dead, then, and not till then, shall my epitaph be written. I expect to live not less than two hundred years. "I shall not pass this way but once, therefore, if there is any good or kindness that I can do any one; let me do it now, let me not neglect or defer it; for I shall not pass this way again."

As President of the Kentucky State Medical Association, I wish to thank you for the great honor you conferred upon me at Lexington, September 28th, 1910. This day has been the happiest one of my professional life. While we need quantitative membership

*Delivered at Paducah, October 24, 1911, 7:30 p. m.

in every county medical society, it is after all, quality and skillful scientific attainments that count most for good to the profession and humanity. The medical profession overcrowded Chicago, February 27th. Dr. Alexander Hugh Ferguson, President of the Chicago Medical Society in an address to members of the Association of American Medical Colleges, said, "The medical profession is overcrowded—it is 'not overcrowded by the 'survival of the fittest' but by the 'survival of the unfit.'" Dr. J. N. McCormack in an address at Savannah, Ga., to the medical profession enunciated these golden truths, viz.: "We want a school for the doctors; doctors should study or quit the practice." Poverty in the medical profession is more dangerous than tuberculosis. There is not a busy doctor in this room to-night that does not pass the life or death sentence on someone at least once a week; many people too poor to have their lives saved under the present conditions. Not enough doctors for the proper treatment—a large part of the doctors of this country should go to studying or quit practice—the country would be better off if 50 per cent. of the physicians in it did go out of business. Every large town and every county should have a weekly post graduate course by the doctors and for the doctors.

A community which kept its doctors in poverty will have a large portion of its people die prematurely.

We want better organization of the physicians of the country; through their local organizations; that the advantage of cooperative study may be obtained; that the lot of the doctors may be made better; that better laws may be enacted; better sanitary conditions maintained; the science of medicine faster advanced and the mission of the physician as he sees it, better fulfilled.

Our conception of the physician is that he should be a leader in the community; the cleanest man in it; clean in speech; clean in his morals; a leader of opinion and the best cultured. The time is at hand, he maintains, when the doctors are to have the leading part in the destiny of the country.

The early legislation in the United States was placed in the hands of lawyers as a rule, because the problems were of a nature which could best be met by men of that profession.

Now, the problems are social and moral and psychological and a different class of men should be sent to the legislature—in this the doctors and teachers must take a hand by impressing on their legislators, the worth of the health measures before them and helping to get men into the legislature who will give proper consideration to these measures.

The organization of a weekly or bi-monthly post graduate course in every town and coun-

ty should be done by the local physicians; every medical society meeting is a post graduate course, this is a golden opportunity of the practitioner to gain knowledge from and impart knowledge to others.

Most of the great discoveries in medicine and surgery have been wrought by the country doctors in Kentucky, Virginia, Tennessee and the South. They achieved in the past; why not we achieve in the present and future? If we all can not hitch our wagons to the stars, let us get in and ride while others do the hitching.

Our fees are too low, few doctors are able financially to buy necessary books, journals, instruments and take post graduate courses in the hospitals of the larger cities and equip their offices as the modern up-to-date skillful practitioner should do.

I say unto you, Sampson! Sampson, awake! awake! the Philistines be upon thee! Do better and more skillful service, save more lives, cure and relieve more patients, charge more for your services and get better pay; remember *now* while you are *young*—prepare for a *rainy* day; for to you the *time may come* when, *you may be old* and in the *way*. Most doctors die poor at the end of a useful and well spent life and as they stand on the mountain top of life, weak with infirmity and old age and poverty their professional sun about to set, and hear the sad, sad, wail and echo over the hill to the poor house.

We should and must have a home for the old doctors, properly endowed and sustained, that we may in the evening of our lives, have rest, support, comfort and solace before we ship for the other shore of God's eternal home.

Oh! my brother, dear, be skillful and useful in the art and science of Hypocrites—learn early how to cut the Gordian knots of professional life and cut as often as it is necessary; remember that a long incision is better than a short one. The miser's pockets needs drainage.

A famous General was asked how he maintained a strategic point during the Civil War? His answer was, "I got there first with the most soldiers and held it." "The early bird catches the worm," but it is hard on the worm—the wide awake, studious, meritorious doctor, skilled and up-to-date, gets the best clientele and the best pay and always reaches the goal—success—sooner or later. If he be an ethical medical society man and takes post graduate courses, he always stays in the van of his profession and will be found in the upper story of his calling, and not crowded by the "mediocres," "the longest poles knock the persimmons," the victory is to the mighty, the swift and the valient in life's battle.

Dr. Alfred L. Loomes, Professor of Prac-

tice in the University of New York City Medical Department, started life a poor boy, educated himself and took the profession of medicine for his life work, and made a National reputation as a pathologist, diagnostician and practitioner and teacher. He was asked how he succeeded so well, he said, "I worked long and late, studied hard, trimmed the mid-night lamp, always did my best and climbed over the shoulders of the poor into the pockets of the rich." Died worth \$1,000,000. Sir Andrew Clark, the great and successful practitioner of London, England, started life a poor boy, was always studious, and did his best—won every position and prize that he competed for; said, "I worked twelve years for bread and butter, twelve years for reputation, and twelve years for fortune. He died famous, his estate was worth (\$5,000,000) five million dollars.

Therefore, let us be up and doing, with a heart for every fate, still achieving, still pursuing, learn to labor and to wait." May it be said of each one of us, in the language of Caesar, "I came, I saw, I conquered."

Every doctor in the Commonwealth of Kentucky must demand of the legislators and senators and Governor, a State Tuberculosis Hospital. We must also demand of our county judges, magistrates, county attorneys, and tax-payers a County Tuberculosis Sanatorium and Hospital in every county seat and in Kentucky. Let us present ourselves living sacrifices true and acceptable to the dear people and teach the great work and problems which daily confront us, for the betterment of the profession and humanity.

We long to see the Department of Public Health established at Washington, D. C., and have a skillful, meritorious physician for the Secretary and Cabinet Health Officer, presiding over this department and the Army, Navy, State and Interstate Health Boards and bureaus all consolidated into one National Board of Health; each bureau continuing to perform its proper functions without conflicting with the others. We must work and co-operate to have all these county, state and National institutions established at an early date, properly endowed, equipped to do the greatest good to the greatest number of suffering humanity; of the people, by the people, for the people. Live or die, sink or swim, survive or perish, I for one, will devote the remaining days of my life working to establish these great public institutions.

It took a long time to establish the Agricultural Department (U. S. A.) and it now spends \$14,000,000 or \$15,000,000, a year in preventing and arresting diseases in animals; the horse, cow, sheep, pig, chickens and other poultry—in arresting and preventing diseases in vegetables, trees, plants; and nothing

is spent by the U. S. Government to arrest and prevent diseases in the wives, husbands, mothers, sons, daughters and fathers. Shame! Shame!

We congratulate the Legislature and Senate and the Governor of Kentucky upon the passage of the bill appropriating \$30,000, to further the interests and urgent demands and necessities of the Kentucky State Board of Health. The appropriation should have been not less than \$100,000. Illinois appropriates yearly \$150,000 for her State Board of Health, Pennsylvania donates \$250,000, New York State also appropriates \$250,000 to her State Board of Health.

We want a legislature and Governor of Kentucky that will vote \$100,000 for the State Board of Health; the same amount for a State Tuberculosis Hospital and adequate sum to equip and make this hospital the equal of any other state institution of its kind; yea it should be the best in the world.

Are not the lives and happiness, success and destiny of Kentuckians as good, dear and sacred as those of Illinois, Pennsylvania and New York states? Of course they are, and we should have and demand of the legislature and Governor the adequate and essential appropriation to meet the necessary demands due our people and the Kentucky State Board of Health.

We count ourselves most fortunate upon having a "bi-partisan" board of commissioners to conduct and manage and control eleemosynary and charity institutions of the State and that this charge was brought about by the Kentucky State Medical Association and doctors of Kentucky, and that the Kentucky State Medical Association nominates three of its competent and expert members for the Governor of Kentucky to appoint one or more or all of these as the case may demand for Superintendents of our asylums and we recommend the members for the State Board of Health and the Governor appoints them.

THE GOLDEN RULE.

We need more physicians in Kentucky to teach and live lives of Damon and Pythias; of David and Johnathan, to teach and practice the code of Ethics, the "Golden Rule". A physician must study right, think right, speak right, do right, and live right and die right. Away with commercialism, *avant!* "Get thee gone thou thief, thou demon!"

GRAFT IN THE MEDICAL PROFESSION.

Any surgeon, specialist or consultant who offers a take out commission for the practitioner is a thief and snogastor. Any practitioner who demands from the surgeon, specialist or consultant a commission or graft, is a thief and snogastor.

We cannot live a dual life; Dr. Jekyl and

Mr. Hyde have had their day, and are back numbers. I do not believe in gonorrheal religion; a syphilitic spirituality; nor a strictered professional life. When a man and a woman marry, each should be legally required to give a clean bill of health before entering into the sacred bonds of matrimony—they owe this to themselves, posterity, to humanity, and the Commonwealth of Kentucky.

Too many homes are blighted, innocent women infected; inoculated and made barren by a syphilitic or gonorrheal husband, and too many women in the past have had to submit to the life-saving abdominal and pelvic surgery. All shame and dishonor to their tainted husbands and physicians; who let these demons of society marry pure and innocent women before they are cured. It is appalling to realize how many babies are made blind from birth with gonorrheal ophthalmia—due to the infected and contaminated husband and father. We believe a syphilitic or gonorrheal person is a criminal and more dangerous to society, his family, his country and business than tuberculosis, whooping cough, mumps, diphtheria, smallpox, and exanthemata, and these criminals should be isolated, quarantined, and confined and wear the scarlet emblem of infection, contagion and danger until cured and restored to society.

The medical profession can and should be a Gibraltar of strength and power, influence, unity, friendship, brotherly love, and protection in the Medical Defense League. We have an harbor of safety from the storms of professional life; black-mailing; illegal persecutions, and malpractice. The Kentucky State Medical Association did a most righteous act when the annual dues were raised to \$2.50 for each member, and more than 2,600 physicians admitted into the Medical "Defense League."

You know not the hour when some unscrupulous, ungrateful patient, with the help of some dirty, and infamous blatherskite in the profession, aided by one or more hungry, wolfish, and disreputable lawyers, will bring a damage suit for malpractice or try a black-mailing scheme, to rob you of your hard-earned money. *Now, is the day of salvation, get into the life boats,* the County Medical Society and the Kentucky State Medical Association and be saved right now, while it is called to-day.

BLATHER AND BLATHERSKITE.

Aesculapius had a brother of whom he tried to make a physician. As a physician Blather was a failure, as a Blatherskite he was a success. He was not studious, but lazy, meddlesome, garrulous, intemperate, selfish, envious, jealous, unscientific, unskillful, ambiguous, given to duplicity—a saint on Sun-

day, a sinner the rest of the week and when away from home, he demanded a commission from the surgeon consultant or specialist, never attended the medical societies, or took post graduate courses—was the instigator of malpractice suits, consorted with malefactors. Aesculapius became so disgusted with Blather, he named him a Blatherskite and Senolagoster and had him expelled from the profession.

Is there not something wrong with the daily professional lives, habits, heredity, characters, and environment of many physicians? We should all practice the "Golden Rule" day by day, then we would have no need of the "Code of Ethics," except as a signboard or morning and evening star of our professional lives.

Let the profession rejoice that four medical colleges in Kentucky have passed away and that in their place we have one; the Louisville University, Medical Department—we should work zealously to make this institution the best and Louisville should be one of the great medical centers of the world. Yet in the future, we look for one more medical college. The Medical Department of the Kentucky State University, with large State appropriations from time to time; properly equipped, will be the equal of any at home or abroad. We have the right to expect great things from these institutions in the future, for the country doctors "blazed the way" about a hundred years ago. Let us pause and behold their works and achievements: Dr. Walter Brashear, who immortalized himself by doing the first successful amputation at the hip joint in America and perchance the first in the world. This operation was performed on a seventeen year old mulatto boy living in Bardstown, Nelson county, Kentucky, August 1806; the boy living many years subsequently. Dr. Brashear practiced the circular method securing the blood vessels, then making an incision over the major trochanter and bringing the head of the bone through this opening. Dr. Brashear moved to Lexington in 1813, attained distinction in his profession, remained there nine years; in 1822 he moved to St. Mary's Parish, Louisiana, here seeking his fortune as a planter and merchant—both proved financial failures and engaging some in politics he abandoned his profession, only rendering service occasionally to his neighbors, and then gratis. He represented Louisiana in the United States Senate, and was a man of great professional and personal popularity. The country doctor who brought the greatest fame to the Country, Kentucky and the World, was Dr. Ephraim McDowell, of Danville, Boyle county, Ky. "The back-woods of America" in 1809. He removed successfully an ovarian tumor weigh-

ing 22 1-3 pounds, the patient was Mrs. Crawford, of Green county, Ky., forty-seven years old. She lived thirty years afterwards. Thirteen ovariectomies, five deaths eight recoveries. Dr. McDowell's office and residence still stands in Danville, Kentucky, and is used for a negro tenement house. All shame to the profession, the citizens, and tax-payers of Danville, Boyle county, and Kentucky. It should be purchased by the tax-payers or some rich man and made the Kentucky Academy of Medicine and Surgery under the auspices and control of the Boyle County Medical Society and Central Kentucky Medical Society. Every Kentucky physician should visit Danville and McDowell's monument, erected by the Kentucky State Medical Society in 1878. "Honor to whom honor is due."

Dr. Charles McCreary, of Scotch-Irish descent, the 7th son of Robert McCreary, born in Clark county, Kentucky, June 13th, 1785, was a great uncle of Ex-Senator James B. McCreary, the latter to be our next "Model" Governor of Kentucky.

Dr. Charles McCreary settled in Hartford, Ohio county, Kentucky, did a large practice in this and adjoining counties, delivered lectures regularly in his home to his own students as well as students of others. His chief operation, the one that makes his fame enduring, was extirpation of the entire collar bone in 1811; the first record made. Case reported in full by Dr. Johnson, in January, 1850, Number New Orleans Medical and Surgical Journal. No doubt the patient had tubercular osteitis or osteomyelitis. The operation was done on a young man, was a decided success, the patient made a perfect recovery, with perfect use of the arm, and living past the middle life; doubtless had a reformation of the clavicle, as he had perfect use of the arm. At Hartford, Ohio county, Kentucky, Dr. Chas. McCreary's grave is handsomely cared for by his grandchildren and he need not have uttered the prayer "Lord keep my memory green."

Dr. Benjamin Dudley, the greatest lithotomist of the nineteenth century, organizer of the medical department of Transylvania University, its master spirit and its professor of anatomy and surgery. He was in 1850 the founder of the "Kentucky School of Medicine" and remained with it until 1857 when he was sixty-five years old—he removed to his farm to pass the evening of his life. He did general surgery; trephining especially, and successfully for traumatic epilepsy; successfully tied the carotid for intra-cranial aneurysm—but Dr. Dudley's greatest success and chief field of labor was the bladder. He did 225 lateral lithotomies for vesical calculus with the loss of but three patients; not hav-

ing a death in his first hundred cases. He prepared his patients by rest in bed; free purgation with Crab Orchard salts and calomel—dieted freely—fed his patients on milk and mush, corn bread and buttermilk. He was a clean surgeon, used much warm, hot, and cold water, the latter from his cistern, and resorted to the free use of the soft or hard lye soap made from ash hopper lye in that day—the ashes obtained from burning the purest and best virgin forest timber. An Englishman alluding to Dr. Dudley is said to have remarked "That it has been reserved for a back-woods man in America to teach how to prepare the patient for a capitol operation." No one ever did so much with the roller bandage, relying upon it even in fractures of which he was emphatically master. Dr. Dudley was born in 1775 in Virginia, died in Lexington, January 20th, 1870.

Dr. Allen Goldsmith, who in Lincoln county, Kentucky, in 1829 performed for the first time in the United States lithotripsy; Dr. Jno. M. Briggs, of Bowling Green, who in 1830 for the first time in this country did hysterectomy—(Dr. Mosely carried out the principles of Esmarch's bloodless operation about 79 years ago) narrated by Dr. Ely McClellan, Philadelphia, Pa.

Dr. Benjamin G. Bowman, of Harrodsburg, Mercer county, Kentucky, to whom may be almost given the credit of having invented the hypodermic syringe, the use of such an instrument by him having been witnessed by Dr. C. S. Able, who in May, 1901, was still living.

Dr. Joseph Taylor Bradford, in Augusta, Kentucky, from 1840 to 1870, was the most successful operator of his day for ovariectomy, 90 per cent. of his cases during this early period of surgery recovering.

Dr. Henry C. Miller, the grandfather of Dr. Henry Goodman, Louisville, Kentucky, lived on Salt River, in Mercer county, Kentucky, in his early professional life; may be truly called the world's greatest obstetrician, having taught the profession how to control post partum hemorrhage by introducing the clean aseptic hand washed with lye soap, the best ever made, and made by the noble pioneer women of Kentucky, into the uterus and turn out clots and remove the placenta and produce pressure both with the hand inside and outside of the uterus; pressure hemostates—"pressure force."

Dr. John C. Craig, Stanford, Lincoln county, Kentucky, the great "County Surgeon," the student and preceptor of surgery for Dr. Samuel D. Gross, Sr., University of Louisville, Ky., Medical Department, was a great obstetrician, lithotomist, ovariectomist, herniotomist, a renowned brain surgeon, oculist and laryngotracheotomist. He made Central

Kentucky and himself illustrious by walking in the surgical footsteps of Gross, Dudley, Brashear, Miller and McDowell, and was twenty years ahead of the profession when he died.

Dr. Breynard, a Virginian, and a country doctor, the father of successful life-saving abdominal surgery for ectopic pregnancy.

The great Dr. Nichols Senn, of Chicago, was born and raised a poor country boy in Switzerland. At the age of 12 years he said to his mother, "I want to be a doctor and a big doctor when I get grown and make \$100 every day." All of which he did do. And his mother lived to an old age, and saw him achieve this great success.

Dr. Joseph Price, the illustrious abdominal and pelvic surgeon and his brother Mordecai, equally skilled but not so illustrious, were country boys raised in the mountains of Virginia, and received inspiration from country life and study.

Dr. Joseph Price has lessened the death rate in ectopic pregnancy from 98 per cent. to 1-30 of 1 per cent—hysterectomy from 95 per cent. to 1-20 of 1 per cent, and has operated on 115 cases of appendicitis consecutive cases, not selected for interval operations with a lowered death rate of 1-15 of one per cent. Dr. Price has performed 135 sections for appendicitis with ruptured appendix, pus in the abdomen with the loss of five patients' lives.

In Caesarian sections, the country doctor has always excelled, have had the smallest death rate; the city hospital surgeon has always had a high mortality. Dr. Joseph Price the country boy of Virginia, now of Philadelphia, has redeemed the city hospital surgeons high death rate by doing 7 Caesarian sections and saving seven mothers and five babes.

Kentucky country surgeons in the past have reached or made noble achievements, and will do so in the future. The late Dr. Nicholas Senn states it is with the aid of the trained nurse that the general practitioner will regain the surgical work that rightfully belongs to him; again, Dr. Senn states, if I had the choice of operating in a most elaborate operating theatre without a trained nurse and in the kitchen of a farmer's house with a trained nurse, "I would not be long in deciding in favor of the latter and I am confident that the patient would be benefited by the preference."

A splendid operating room with elaborate facilities for sepsis is desirable but not essential to obtain the best results, therefore, county doctors, *semper paratus*—demand your rights.

The medical profession is crowded, there are surplus of doctors, but there is much

room in the upper story. Climb higher! climb higher! onward and upward.

NOBLE PROFESSION—POOR BUSINESS.

Our profession is a noble calling but is a poor business, only one physician in ten engage in medicine as a life work, only one in fifty makes a success, one in five hundred becomes distinguished—makes a state and national reputation.

Each physician to make a decent living must have a population annually of twelve hundred clientele. Yet in Colorado, Arizona and California there is one doctor to every two hundred and fifty people. In other states the ratio is one doctor for every six hundred people.

The salary of the average preacher is six hundred dollars annually, that of the doctor is eight hundred. Out of this pitiful sum the doctor is expected to attend medical societies, take post graduate courses, buy best Journals and books, keep abreast in his profession, support and educate a family. It couldn't be done in the past, and the present, and it cannot be done in the future.

The future demands fewer doctors and more skillful doctors, and better paid doctors than ever before. Of necessity more and more doctors will retire or be retired by the people from incompetency.

Doctors who have made a financial success have done so in other lines of business, or have inherited or married wealth.

Either be a success or retire before you become a blatherskite or a senolagoster in the profession.

Carlyle says, "The race of life has become intense; the runners are treading upon each other's heels, woe to him who stops to tie his shoe strings." In every walk of life to-day it is a matter of the survival of the fittest. Roosevelt says, "The world wants men and women who can do things."

A law of worthy life is fundamentally the law of strife. It is only through labor and painful effort, by grim energy and resolute courage that we move to better things. We all have a task to perform, a goal to reach. Russell states, "No man can be happy without being industrious." We have all set sail on the stormy sea of life, full of hope and devotion, guided by the Elder Brother, The Great Physician. May the prayer of the Briton sailor, when he puts out to sea, be ours, "Keep me, my God—thy ocean is so great and my boat so small."

Benjamin Franklin said, "It is more difficult for a man in want to act honestly, than it is for an empty sack to stand upright;" David said, "Man is as prone to evil as the sparks are to fly upward." These two aphorisms may explain why the Code of Ethics—the Golden Rule—is often violated

by many in the profession. Always do your best for your patients, profession, family, and country; charge well for professional services, collect promptly, courteously and bravely, pay debts promptly, make good paying investments; carry enough life insurance in old line insurance companies; provide for self, family, sickness, a rainy day, and old age. Be your own administrator while you live for when you shall have passed away, your family will be robbed of many an honest dollar you earned and have charged on the ledger.

It is surprising how many people will try to disprove the medical account after the physician, who rendered the services is dead. Collect to-day, to-morrow, and the day after to-morrow.

Every physician should be an example in his own community for thinking right, speaking right, and acting right, and he should be the builder of his own reputation and fortune. It is a great misfortune to most doctors to have much wealth during their student days and the first five or ten years of professional life. Nothing develops a young professional man like judicious poverty and hard, earnest, meritorious labor. Money stunts, pauperizes, paralyzes and produces indolence, intemperance, immorality, and many other vices. Benjamin Franklin states, "Nothing is so likely to make a man's fortune as virtue." He urges us to make money, because, if we are prosperous people will respect us. He says, "Now that I have a sheep, and a cow, everybody bids me good-morning."

No doctor can afford to be slothful, for the sloth like rust, consumes faster than labor wears. Franklin also says, "He that is slothful in his work is brother to him that is a great waster." A doctor who collects promptly may make some enemies, but, should be admired and praised, for the enemies he makes rather than cut bills into halves to make it appear he is a cheap doctor and buy future favors with patients. Your superiors will never envy or hate you or be jealous of you; but your inferiors will. It is the ignorant, incompetent, and inferior physicians who deals in envy, hate, jealousy, backbiting, and slander, and the aid of the disreputable lawyer in bringing malpractice suits against the worthy physician. Let us be studious, meritorious, gentlemen, Christians, the highest type of American citizens, then we will practice the Golden Rule, think right, speak right, and do right, live and die right.

Consultations are first, for the benefit of the patient, second, the family, third, the friends of the patient, fourth, for the physician, fifth, to protect the attending physician and share the responsibility. Holy writ and law of our State affirm that from the mouths of two

witnesses every word shall be established.

In the past, many physicians have been too small, ignorant, and selfish to call for a consultation or allow the patient or family the privilege of a consultation. Grant right and liberty to every man, woman, and child.

According to the constitution of Kentucky and the United States, every person, well or sick, has a "bill of rights" that should be respected by every physician. The essayist has determined, long ago, to respect these courtesies, and rights, and liberties of patients, family and colleagues and demand the same for himself and every gentleman and American citizen will do likewise. If the professional brother offend thee, forgive him, spitefully use you, bless him, curse you, pray for him, has no money, loan him some, has no practice, help him to get practice, hungry feed him, naked, cloathe him, sick or in prison or distress, visit and comfort him! do unto him as you would be done by; not for the glory of self, but, for the glory and good of the other fellow and the glory of God.

My brother lay down that professional handspike and get the beam out of your own eye before you prize the mote out of your brother's eye. Get right with God and yourself, then you will get right and keep right with your brother physician.

The sun, moon, and stars each have a glory—yet, and the firmament thereof all declare the glory of God and so should the doctors.

As the stars, the sun, and moon differ one from the other in size, light, form, beauty, brilliancy, and grandeur; so will doctors differ in their Christianity, industry, erudition, skill, wisdom, professional achievements, diplomacy and financial success.

Two phases include the entire domain, viz: First, seek ye the Kingdom of Heaven and God's righteousness, and these things shall be added unto you; the latter phrase, is, Hear the conclusion of the whole matter, "Fear God and keep his commandments."

If we desire heaven, we must seek it here—if we love heaven, we must love it now; Heaven means holiness. Heaven means principal. Heaven means to be one with God.

Simplified Tuberculin Skin Test.—Barabasechi rubs the region with alcohol until the skin is red. Then in the center of this area he spreads a thin layer of tuberculin without rubbing it in and lets it dry. In 114 cases in which he has applied this test there never was any general reaction, while the local reaction seemed to be a reliable index of an active tuberculous process even when the process was in its incipency. He gives the details of eighty-nine cases to show the reliability of the test. His previous communication was summarized in The Journal, Sept. 10, 1910, page 977.

MEETING COUNTY SOCIETY SECRETARIES**ASSOCIATION OF COUNTY SECRETARIES AND ASSOCIATE EDITORS.***

OCTOBER 23, 1911.

After the adjournment of the House of Delegates of the Kentucky State Medical Association at 4 p.m., the Association of Secretaries of County Societies was called to order by Hugh D. Rodman, Vice President, in the absence of the President, D. O. Hancock, of Henderson.

L. H. South, Bowling Green, presented her report as secretary.

The minutes of the previous meeting were read and approved.

T. A. Frazer, Marion, read a paper entitled "How to Assure a Program for Each Meeting of the County Society."

W. A. Poole, Henderson, read a paper entitled, "Special Meetings, Public Meetings, General Meetings, Proper Subjects for Discussion; Their Mission."

W. W. Anderson, Newport, read a paper on "How to Prepare a Program for the County Society for the Entire Year."

It was moved that all of the papers be read first and then discussed.

Motion seconded and carried.

D. O. Hancock, Henderson, read a paper entitled "What is the President of the County Medical Society Good For?"

W. W. Richmond, Clinton, read a paper entitled "What Would Happen if Every County Medical Society Were a Good One?"

**WHAT CAN WE DO TO MAKE THE
COUNTY SOCIETY MORE EFFECT-
IVE AS THE INTEGRAL PART
OF OUR STATE AND NA-
TIONAL ORGANIZA-
TIONS.***

By T. ATCHISON FRAZER, Marion.

Since the organization of the London Medical Society in 1775, there have been divers plans promoted for the more effective medical society work.

This subject has baffled the efforts of many of our best medical men; but, as time goes by, and as medical science approaches nearer to the exact, and the demands upon the profession become more exacting, the more we feel the necessity of a more compact organization and the crying need of physicians to come in closer contact with each other in the study and practice of medicine.

The physician who is isolated, who practices medicine to himself, we might say, must of necessity, be a man of very broad mind and character if he does not get into "ruts" and

keep in them, if he does not grow smaller instead of larger. The only feasible way to prevent this deplorable condition, is through the well organized Medical Society.

The County Society is the bulwark of the general practitioner. The scheme of medical organization in this country is the greatest professional organization in the world. The greatest good to the greatest number of people, is the primary object of medical organization. There are no selfish aims; there is no narrow bigotry nor molly-coddling in medical organizations, notwithstanding the rantings of the various "sects" and "League of Medical Freedom."

Physicians are like silver dollars—the more they are rubbed together the brighter they get. Therefore, the best place to rub them together is in the County Society.

Now comes the important question, "What can we do to make the county society more effective as the integral part of our State and National organizations? This subject being assigned to me, reminds me that "Old maids and bachelors" can give the best advice as how to rear children. It seems to me that I have made a dismal failure as secretary of our county society, and that some one, who has made a brilliant success of society work would have best answered this question. My experience as secretary of several other organizations, has taught me that more responsibility rests upon the shoulders of the secretary than upon any other officer of any organization. The success of all organizations primarily is in the hands of the Secretary; he holds the reins that guide the chariot to success or failure; he opens the throttle that causes the engine to move, he closes the throttle that stops the motion of the engine.

The secretary of the county society should keep on friendly terms with every physician in his county, he should have no grievance against any one. He should stand ready to make any sacrifice to facilitate the work of the society; yet, he should be firm in what is just, deliberate in all his official acts; counsel his fellow physicians as to the wisdom of all acts pertaining to the work of the society. He should strive to make each member feel that he is a part of the organization, and that his co-operation is necessary to its success.

Doctors are usually good fellows, but jealousies often arise because they do not know each other. We should strive to bring the members in close touch with each other, in order that they may know each other better. We often dislike a certain doctor because we do not know him as we should. I think the post-graduate system of study, as outlined by Dr. Blackburn is the best plan of study for the county society; but, in small counties there are so few active workers that it is hard

*Read before the Association of County Secretaries, Paducah, 1911.

to carry out this plan of work. But I see no reason why it should not be a success in the larger counties.

A program should be prepared with great care, for each meeting, and the secretary should be prompt in sending it to the members. Sometimes we can get a man in the harness by asking him to read a paper, the subject of his own selection. Other times when a doctor is put on the program, he will refuse to attend the meeting as long as his name is on the program. So it takes a great deal of diplomacy to handle these subjects.

The subject of the collection of dues is a very important one, and the responsibility for this work rests entirely upon the secretary. Written notices should be sent to each physician but I find the better plan is to see the members personally when possible, and insist upon the importance of their paying their dues promptly.

We should insist that we get value received in our State Journal for all our membership costs us. We should try in every way possible to convince the profession that medical organization and society work are personal helps, and ultimately put dollars in our pockets.

If we can get a doctor to realize that there is something for him to do, and that no one else can do his work then he will generally get in the harness; this personal responsibility is absolutely necessary to a good society worker. The national organization with its integral parts is an organization that has for its chief purpose the uplift of humanity, the eradication of preventable diseases, and the betterment of humanity. The Kentucky profession is the equal of any state in the Union and it should be the ambition of every Kentucky doctor to make it the best on earth.

SPECIAL MEETINGS, PUBLIC MEETINGS, OPEN MEETINGS, JOINT MEETINGS; WHAT ARE PROPER SUBJECTS FOR DISCUSSION AT THEM AND WHAT THEIR OFFICE.*

By W. A. POOLE, Henderson.

We will attempt to discuss these four meetings in the order named.

Special meetings should be held to discuss any subject that concerns the profession which cannot be put off until the regular business meeting or which could not be properly discussed in the short time allowed at our business meetings.

Much has been written about the division of fees and every county society might find it profitable to make this a subject of a special meeting and settle the question finally.

A movement started in Iowa last year, to establish business bureaus for county societies with an attorney who would make a systematic attempt to collect old bills, might be discussed.

In cases of epidemics special meetings to discuss conditions may be found helpful to the members of the profession.

Special meetings from time to time to discuss general subjects, such as, to request local papers not to run patent medicine ads., etc., in the news columns.

When we can arrange to have prominent men to read papers on special subjects it often stimulates our members to renewed efforts to accomplish something.

The purpose of special meetings is to benefit the members themselves and bring them closer together in a social and scientific way.

PUBLIC MEETINGS.

We may first inquire into the value of publicity in general and its adaptation to the prophylaxis of diseases.

Recent developments have demonstrated its remarkable value in the correction of certain public, political, and commercial evils. The essential conditions for the existence of these evils is the ignorance of the public.

It may be claimed that the public is indifferent even averse to this enlightenment. Less than ten years ago the public was indifferent to the dangers of tuberculosis, but it was only necessary to correct the ignorance, the cause of this indifference and public apathy was at once transformed into an active interest.

Public interest in the drug question has been aroused by the warfare against the nostrum evil. This crusade was started by public health defense leagues organized by the public and not the medical profession. It was the enlightenment of the public through Collier's and other lay magazines that has caused these people to be ready to assist in checking the great American fraud, not only as it applies to patent medicine, but to quackery and fraud in general.

The problem of a pure milk supply always interests the public.

Under existing conditions there is undoubtedly gross neglect of sanitary precautions and cleanliness.

The abolition of the public drinking cup is a sanitary measure of real importance that has been adopted rather widely within a short time and the public should be educated to the danger of common drinking cups.

The attitude of the general public is known to be strongly antagonistic to the establishment of prohibitory restrictions that insure

*Read before the Association of County Secretaries, Paducah, 1911.

protection against certain communicable diseases. The ignorance of the public concerning the cause and development of disease, and the laws of hygiene and sanitary science is the cause. Once the public is sufficiently aroused to comprehend and appreciate its own interest in this question little will be required to assist us in the prosecution of this work.

The public should know more of our code of ethics as it would place the profession in a better light before the public and often prevent confusion and ill-feelings between the members.

The Russell Sage Foundation is offering us an affective example of the good that may come of educating the public in the care and feeding of infants.

The fact that blindness is often preventable makes it imperative that we discuss this subject in our public meetings.

The number of deformed children we see on the streets should be an incentive to cause us to instruct parents how to prevent many of these conditions, and to correct others.

OPEN MEETINGS.

In the fight against preventable diseases there has come a time in the history of each one which has been systematically attacked, and it seems that the prevention of cancer must be regarded as a practical problem ripe for solution.

Lantern slides illustrating the anatomy and life history of the hookworm disease have been prepared by the hygienic laboratory of the U. S. Public Health and Marine Hospital Service to be loaned to medical societies.

Pellagra is another disease that is attracting the attention of the people and they should have a chance to get correct information concerning the disease from our open meetings.

Likewise infantile paralysis should be discussed at open meetings.

It is the united sentiment of modern students, that as a measure of public safety if for no other reason, the public should be taught certain facts regarding venereal diseases. It is not confined to the torrid of prostitution where it originates. It collects about the very sources of human existence, it pollutes the fountain of life, it befalls the social function of maternity, its defilement clings to the innocent child ushered into the world. If the medical profession should share with the people the knowledge it possesses of the frequency of such infections and their terrible consequences to the health and lives of innocent women and children, an awakened public sentiment and an aroused public conscience would no longer tolerate such social infamies.

JOINT MEETINGS.

Dr. W. H. Snyder, Toledo, Ohio, says: "If the profession had not lived so much within itself, but rather had spread its ideals and discoveries before the public, anti-vivisection, Christian science, Osteopathy, Optometry, and mental healing could not have gained ground except with those who are mentally incompetent. Well known monthly and weekly magazines have during the past two years probably done more to educate people along correct lines of medical thought than any other agency. They reach a larger number of people who must see in cold print what is intended for them to know." We believe this would be even more true of the local papers if the county societies would meet with the members of the press and let them know what we are trying to accomplish.

The county societies in Missouri, last year began active co-operation with the teachers and organized teachers' reading circles, that meet from one to four times a month, and which adopt every year a book for study.

The possibilities of close co-operation between the county medical society and the county teachers organization are practically unlimited.

Members of Boards of Education, Superintendents, principals and teachers of schools both public and private, should be well informed as to the nature of venereal diseases and the dangers which attend them and their interest and co-operation secured in efforts to check their ravages.

Medical inspection of schools should be discussed and a campaign of public education started. It is evident that school inspection cannot be a success unless the parent is instructed and interested in the nature and objects of medical inspection. They should be taught in a general way the significance of the defects and diseases to which their attention has been called. This interest was aroused in Boston in 1905 by organizing parent-teacher associations, the parents were instructed concerning the care of their children by lectures on the physical development of the child.

The venereal diseases, their cause, prevention and cure should be discussed before the Y. M. C. A.

Effective work can be done through church organizations, young people's Christian endeavor societies, mother's meetings and the Salvation Army to bring about any reform.

Joint meetings should be held with the clergy to discuss health conditions and other things of importance to the public, for instance: In the September 3, 1910, number of the *Journal A. M. A.*, attention was called to the fact that "Vitae-Ore" became popular by advertising in the religious papers. Such

conditions could be remedied after discussing them with the clergy.

Counter prescribing by the druggist cannot be stopped at present but by frequent joint meetings with the druggist we may have such understandings of good intentions as to curtail the practice. The relations of the doctor to the druggist and druggist to the doctor should be discussed and U. S. P. and N. F. preparations reviewed.

Medical expert testimony is a puzzling problem for physicians, lawyers and judges. Our state society has a permanent committee on this subject and we may soon have some valuable legislation but our county societies will benefit by discussing this subject with the county bar association.

A meeting should be held with the dentists to discuss relations the two professions bear each other.

Woman's clubs will help materially to bring about medical inspection of schools, the establishment of infant milk depots, securing nurses for the poor, etc.

Joint meetings should be held with anti-tuberculosis societies and all other societies for prevention or cure of disease or of interest to public health, and scientific advice given them about the conditions in which they are interested. The civic societies should have the co-operation of the medical society in many phases of its work especially regarding selections for public play grounds, baths, etc., and in questions like smoke, etc., and in all questions of public instruction.

It is especially in the matter of public instruction and enlightenment, that the medical profession as an organized body fails to meet its true responsibility.

WHAT IS THE PRESIDENT OF A COUNTY MEDICAL SOCIETY GOOD FOR.*

By D. O. HANCOCK, Henderson.

"In the school of Pythagoras it was a point of discipline that if among the probationers there were any who grew weary of studying to be useful, and returned to an idle life, they were to regard them as dead; and upon their departing, to perform their obsequies, and raise their tombs with inscriptions, to warn others of the like mortality, and quicken them to refine their souls above that wretched state."

We often observe a doctor useful as a member of the county medical society, serving efficiently on important committees, writing papers, and even wide-awake as secretary of his society, elect him president and it is time to perform Pythagorean rite. This is not as

it should be. The president of a medical society should be the real head of the organization. He should be elected to that honorable position because of his fitness for it. What he may have done in the past should be considered, only, as it is evidence of what may be expected of him in the future, but, in revised and enlarged edition.

I have attended a medical society where the president occupied the chair and performed in a perfunctory way, a mere "figure-head." The secretary was the "whole show." I have known a president to have very little to do with any of the planning of the work of the society. He would say, amen! if all went well; if not he would stay at home. But this is all in negative. What is the president good for? What are some of the things which he can do and which he should do?

Section 2, Chapter 3 of the Constitution and By-Laws reads: "The president shall be the real head of the profession in the county during the year, and it shall be his pride and ambition to leave it in better condition as regards both scientific attainment and harmony than at the beginning of his term of office."

The president, vice president, and secretary constitute the committee on program and scientific work. The president is named first and is chairman. It is his duty and it should be his pleasure as well to plan for getting essayists and other scientific work for each meeting. A good plan is to outline the work for the entire year and have this annual program printed in nice folder. If sufficient number of them are printed, the secretary can use them in one cent envelopes as convenient notice of each meeting, to be sent to the members about two days ahead. It is not sufficient to thus arrange a program for the year. Each meeting must be looked after and where a failure is imminent secure other talent. No meeting should fail for lack of essayists. This is the work and duty of the president. Often he shifts it to his secretary but it is wrong. The president should visit the membership often in their offices. Talk with them and keep in touch with every thing that is going. Knowing the pulse of the profession he will be able to do much in bringing up the work and securing harmony. He should remember that scripture, "He that repeateth a matter separateth very friends." Men have not learned to come in sharp competition and at all times keep perfectly composed. If a rash criticism is made he can often "Pour oil on" and prevent a rupture. The real secret of harmony in the profession is to be actively engaged in some good work. This is the day when we invite the public into our confidence and give them the "Secrets of our calling." To plan public meetings with other societies, teachers, ministers, druggists, law-

*Read before the County Secretaries' Association, Paducah

yers, and other public spirited citizens is a fruitful resource of a president of a medical society in keeping up interest and prompting harmony.

What is a president good for when he becomes ex-president? This is the saddest question of them all.

"Nothing in this world is so good as usefulness. It binds your fellow creatures to you, and you to them; it tends to improve your own character and give you a real importance in society, much beyond what any artificial station can bestow." The new ex-president is but a graduate in the school of usefulness to the county medical society. It is a sad waste of energy if his attitude to the society now becomes one of innocent desuetude. He should now know how, and the importance of being prompt and responsive to all the needs of the society. He should study the subjects announced and be ready and efficient in discussion. He should, himself, write papers more frequently than the others for he is now matured in judgment and experience. He should be wise in the councils of his society. There are many questions that present themselves which demand his ripe years. Questions of ethics, of harmony, of protection against damage suits; and worse than this, damaging attacks on the profession. Then, too, there is the progressive side. Preventive medicine is fast changing our attitude as public men. Treatment continues to approximate an exact basis. The county society is the unit of organization of state and national efforts to the betterment of conditions of human life. The county medical society is the post-graduate school of the medical profession. I say this advisedly, and without thought of being contradicted by any thinking doctor. Its president and ex-presidents have a duty which can not be neglected by them, or shifted to another with honour.

"Have I done anything for society? I have then done more for myself. Let that question and truth be always present to thy mind and work without cessation."

HOW TO PREPARE A PROGRAM FOR THE COUNTY SOCIETY FOR THE ENTIRE YEAR.*

By W. W. ANDERSON, Newport.

The subject assigned me seems to take for granted the desirability of such a program. Perhaps we are not all agreed on that point. Certainly some societies have not adopted the plan of long-advance programs, for we read in society reports that "Dr. X read an excellent paper on pneumonia and Dr. Z was assigned as essayist for next month and is to choose his own subject." It would appear that some societies do not believe in long prep-

aration or are so poor or so shiftless as to be reduced to the necessity of living from hand to mouth.

One month is entirely too short a time and one year is not too long in which to prepare to do one's subject and one's self justice before a scientific body.

The short-notice paper is usually a poor one that is hardly worth going to hear. Sometimes it is very good but so evidently copied wholesale as to lack all the zest and force of originality. Again it is an old paper read elsewhere before and resurrected for the occasion; but a good cook does not like to serve a warmed-over meal and good feeders do not like to eat it. Wherefore if a scientific feast is desired give the cook ample notice, good material and plenty of time.

The making of a program is governed by certain principles whether the time it covers be long or short.

It must meet the needs of the society by inviting consideration of such subjects as concern the members in their work.

It must be fitted to the ability of the members as a whole and as individuals, as speaker and as hearers.

It should contemplate dependence chiefly if not wholly upon the member for doing the work. No doubt a dry land duck would enjoy having water poured on him but to get the full benefit he must get in the swim and do his own paddling.

No ready-made program, no matter how successful elsewhere nor how highly recommended should be adopted. Dr. Blackburn's outlined course of post-graduate work is probably the most complete and systematic program in existence. Some county societies have prepared and published excellent programs. None of these should be adopted. They may very well be adapted. They may be used as a basis or as suggestive and so changed as to adopt them to the needs and the ability of the society.

The making of a program should not be left to the secretary alone. A one-man program is very liable to running in a rut. A broader program will be made by collaboration and it will also better win cooperation.

The program should seek to give every member a duty and a hearing but should not load itself with dead timber.

It is a good plan to send to each member a reply postal requesting an answer whether he will take part in the proposed program, his choice of subject or his willingness to accept any assigned and also suggestions as to subjects he would like discussed in the meetings.

These replies will furnish a list of subjects and essayists that can be relied upon fairly well. They will also show the lines of the thought that are predominant in the society.

*Read before the Association of County Secretaries.

and suggest other subjects needed for rounding out and completing the program.

For further subjects the committee may well have recourse to the list of current medical journals and other society programs to find suggestions.

In every society there are a few capable and willing workers who will take the trouble to prepare and supply a paper on any subject that is needed to fill out or properly balance a program.

The program should be printed and in the hands of every member before the beginning of the year in convenient form to be carried in the pocket or call book, where it will be a constant reminder and call to duty.

The order of business provided for the meeting should always allow opportunity for the presentation of clinical cases, specimens and case reports and this class of work, at once the most interesting and most instructive should be much encouraged.

When for any reason the essayist fails in his turn the stronger members, the officers and the program committee should be prepared with case reports or other good material to fill the gap.

After all it is much easier to make a good program for a year in advance than to make good with the program at each meeting. The best possible program will not work itself. It requires live, interested, working members held to it by capable officers.

WHAT WOULD HAPPEN IF EVERY COUNTY MEDICAL SOCIETY IN THE STATE WERE A GOOD ONE?*

By W. W. RICHMOND, Clinton.

The improved efficiency of the medical profession has as its object the health of the people. Any other than an unselfish motive would be unworthy of the time and expense of the meetings. The people are the beneficiaries of the work of good doctors; for it is by the doctors that they are taught the laws of health and the ways and means for the prevention of disease. Then the people are dependent on the skill of the doctors to aid them in the time of sickness. So, whatever adds to the efficiency of the doctor is of great importance to the people in giving more information to prevent disease and premature death. Therefore, a good county society would do this and would be of incalculable benefit to the people as a means of better health, less sickness and fewer deaths.

A good county society would increase and strengthen the social condition of the doctors

and in that way, dignify the profession. The careful preparation and public reading of scientific and practical papers, as well as their discussion, edify and improve the physician and lead to greater activity in the study of medicine. Thus, he would be helped in the larger realm of citizenship. His character is strengthened and he is better qualified for his professional duties. It also inculcates a greater desire for knowledge. Members soon realize that they aid each other in society work. So, a good county society would be a means by which a doctor could qualify himself for enlarged usefulness and it would enable him to rise to greater distinction and at the same time aid his brothers to do the same.

A good county society is an organization which should wield a great and beneficial good in a community. It would be a power for good in all that pertains to the medical profession and in all that tends to the welfare of the people. It would show the people that the doctors are progressive and doing their best along scientific lines to safeguard their health. It would prove that the medical profession is interested in something infinitely beyond a desire for personal gain. The good county society would broaden and strengthen the local profession and qualify it to teach the great questions in medicine which concern the people, in that good health and long life depend upon them. Through its influence a hearty co-operation of the people could be secured. A united effort of doctors with the co-operation would make it possible and easier to secure the passage of wholesome laws for the establishment of a proper system of sanitation and hygiene, and for the protection of the people from disease and premature death.

If there were a good county medical society in every county in Kentucky, it would help to make it possible to have better county and state officials who would conserve the best interests of the people in matters of health and hygiene. It would help to make it possible to have better county judges and better members of fiscal courts, men who would be free from prejudice and disaffection and who would have sense enough and judgment enough to consider the health and lives of their fellow beings. It would hasten the time when each county in the state could have an efficient health board, and a properly trained health officer employed on a salary sufficient to enable him to give his full time to the duties of his office.

The county society is a component part of the state association and therefore, is far-reaching in its influence and whatever it should accomplish by reason of its efficiency, would go to increase the power and influence of that body. Therefore, if there were a

*Read before the Association of County Secretaries, Paducah, 1911.

good county medical society in every county in the state, it would help to establish, maintain and control a system of sanitation and hygiene sufficient in every way to reach the source and cause of all contagious and infectious diseases and provide adequate means for protection against the same. Kentucky would not only be noted for her natural resources and rich products, but would be made more famous on account of her freedom from sickness and disease and the health and happiness of her people.

In conclusion, let me say there is no reason why there should not be a good county society in every county in the State, and with a little more zeal and a little more energy upon the part of the profession the feat can be easily performed.

DISCUSSION ON PAPERS PRESENTED.

J. G. Carpenter, Stanford: In regard to the medical society asking a man to manage the profession in his county, I would say, first of all, that man should be a leader; at the same time, he should be a politician and a humanitarian. It would be a good thing if he would step up to a brother practitioner whom he desires to join the society and say to him, "I am going to dinner with you." I have said to practitioners how much more they would be thought of if they only attended the meetings of their local and county medical society. I have not infrequently said to doctors, I am going home to dinner with you, and am going to stay all night. Doctors, as a rule, have wives of very fine education. I tell them my mission and how their husbands ought to belong to the local and county medical societies, and how much more useful they would be to their wives and children if they attended these meetings. Through the influence of the good wives we have induced many doctors to join local and county societies, a thing perhaps we could not have accomplished otherwise. When they join a medical society we open their eyes as to the possibilities of the great good they can do. Through them we can arrange to have social talks and talks from the pulpits. We tell the non-members and their wives what a rich harvest is to be reaped by being medical examiner for an insurance company. (Laughter). It is a great and important matter to educate the people. It can only be done gradually. There is one thing about free salvation, and that is, while people like to have it, they would rather have a free dinner, they will go and perhaps become members of the medical society if some doctor will foot the bill.

But some doctors do not always have the necessary money to pay for it. A great many doctors, if they were assured they were going to have a free dinner, they will go and perhaps become active members. If you can teach doctors banking, finance, how to make money, and how to save money, and that membership in the local and

county societies will make them rich, they will come. (Laughter). If you give doctors a free dinner, you will find them sleeping together, and when you get two doctors sleeping together, they are all right. (Laughter). They come to know each other better, and although each one may have heard unpleasant things that were said about him, they soon forget that, and like David and Jonathan they go down life together and realize it is a good thing to become members of the county medical society.

M. M. Moss, Franklin: I have been a member of our county society and our state medical association for many years. I have been a delegate several times. I have attended the meetings several times. I believe this is the first time that my voice has ever been heard in a discussion on any subject, although I have been a good listener all my life. I have been unfortunate in not having been president of our county medical society, but have been the secretary of our society ever since I have been in the county and have been practicing there. As secretary of the county medical society, I do not think I have missed a meeting except when I was sick or was away in attendance upon a medical society meeting somewhere else. I have always encouraged our county practitioners to join the county society. Personally, I attend not only the county societies, but State societies, and the National society. I make it a rule to attend these meetings, and while I am very busy sometimes, I do not consider myself too busy to attend a medical society meeting. In talking to some practitioners they will tell us that it is a great sacrifice for them to attend a meeting, but I have noticed that it is the busy doctors who can afford to go to these meetings. The men who are too busy to go to a local medical society meeting or to a county society meeting are generally the ones who have time to go anywhere. That is my opinion of them. But the man who attends his county, state tri-county society, or the national medical society, is usually a busy man between times.

Last week I went to Nashville and attended the Mississippi Valley Medical Association, spent three days there with great profit among my fellow practitioners. I found this meeting of great advantage to me. As secretary of my county society, I encouraged some of our members to go to this meeting, and, by the way, I was successful in getting five or six of them to go to Nashville as it was close by. They told me that it was the most profitable meeting they had ever attended. Whenever I feel inclined to go to a medical society meeting, it does not make any difference how busy I am, I simply put my work aside and go, and I nearly always attend the state society meeting, unless there is sickness in my family that keeps me away.

Vernon Blythe, Paducah: I have been secretary of the McCracken County Medical Society for two or three years. Perhaps it would be bet-

ter for me to say that I was the secretary of this society, but am not now. Three years ago, out of fifty-nine members of the medical profession in McCracken County, our enrollment did not amount to more than thirty-two or thirty-three, and under some trying difficulties we have succeeded at the present time in enrolling all but three of the doctors in McCracken county. If you will look over the statistics of the various counties of the State and the proportion of doctors in each county of the State, you will find that is a very favorable showing for any county in comparison with the other counties of the State. The secretaries of the county societies have a large burden to bear. They have to be peacemakers, and they have to do many things that inwardly they do not want to do. They have to perform a great many peace missions, but by constant vigilance and constant effort in keeping the members informed as to the various duties they have to discharge, by constantly giving them something to do, I find it is one of the best means of gathering strength in any organization. It is important to get every member busy. Make the members realize that they are a part of the organization, and that it is their duty to read a paper now and then and to discuss papers. When they take interest in these things the organization is materially strengthened. One of the hardest features that the secretary has to contend with is to get the various members to write and read papers. I found it was very difficult oftentimes to get the members who were willing to write papers, and the sundry excuses they made were sufficient almost to confound almost anyone; but it requires considerable patience to be the secretary of a county medical society. I appreciate the honor of having been secretary of the McCracken County Medical society, and I feel that my efforts and those of the President were not without avail. I am always thoroughly interested in the work of the county society, and I believe every doctor should make every effort he can to visit these organizations and keep in touch with them and produce harmony just as much as he can in all conditions and other walks of life.

Arthur T. McCormack, Bowling Green: The matter of securing editorial writers for the State Journal is one of great importance, as has been pointed out by Dr. South. Our difficulty, however, is not so much in securing men who are willing to have their names printed on the first page of the Journal. There is not the slightest difficulty about that. In fact, there is never a declination; but willingness on the part of a man to study a subject thoroughly and write a signed editorial on it is a different proposition. We want for our editorial department editorials on subjects that have been very thoroughly studied and digested by the writers, giving us the results. So far as the State Journal is concerned, I do not care so much for abstracts, because I think

the Journal of the American Medical Association occupies a larger field in this regard and undertakes to abstract all important articles which appear from time to time in the different weekly and monthly medical journals. There is no necessity for us occupying a field such as that which can be better covered and more ably handled by such a journal as the Journal of the American Medical Association. What we want, for instance, is for some one to take the subject of pellagra, thoroughly study the literature of that subject, and then write an editorial giving the readers of the State Journal the latest views in regard to it. Personally, I find there is no one who knows anything definite about it. I have read five or six volumes on the subject, but I have seen no paper that has presented anything original in regard to it. A great many articles have been written with reference to pellagra, but they do not seem to throw any additional light on the subject. If we could get some member of the profession to digest some subject thoroughly and write it up for the Journal, we would like to publish it as an editorial, and he need not be particular whether his name is at the top of it or not.

One remarkable thing which is typical of professional conditions, is that we have found it practically impossible to get articles on therapeutics and materia medica. For a long time I have written more letters in reference to these two departments than all of the other departments for the purpose of getting articles to be published in the Journal and have secured less results. For a while I was a little puzzled to find out the cause of that, but I think I have it solved now. There are not enough doctors that know enough about it to write on it. So many practitioners nowadays devote themselves to surgery, that there are comparatively few practitioners practicing medicine with a knowledge of what they are doing, particularly when it comes to the use and action of drugs. For instance, it is a difficult matter to get a man to write a paper on tincture of digitalis. Men like Dr. Ellis, who give medicine, know its physiological and therapeutic action, while the younger men are prone to use mixed tablets. They do not know what the effect ought to be and cannot tell what the effect is. The doses are measured by the pharmacist and not for the patients, or the medicine is given without the slightest idea of what is the matter with the patient. We have gotten away from the point where we can furnish and publish well digested editorials on these subjects for the Journal. I speak for the members of the council when I say that we are very glad indeed to have some one who is willing to write editorials on this or any other subject. We would be glad to print everything for them. So far, we have printed every article that has been furnished by a county medical society; but we would like to have an editor in the Department of Therapeutics

and Materia Medica, and if any of you know a man who is well qualified along this line, we would like to get him.

Alexander R. Craig, Chicago, Secretary of the American Medical Association, was called upon to discuss the papers. Dr. Craig said: A number of years ago I was so unsophisticated as to think that there was but one state medical society that was nearly perfect, and that society was Pennsylvania. I was born and raised in that State, and I thought that Pennsylvania was pretty nearly the right state, and I thought that because away back in the history of the American Medical Association Dr. John L. Atlee suggested, instead of having the American Medical Association, a confederation of delegates from schools and from medical societies. If I remember rightly he suggested a confederation composed of state medical societies and of county medical societies. But some ten years ago I met Dr. J. N. McCormack and then began to learn that here was, at least, another society that equaled, if it did not surpass, the Pennsylvania State Medical Society, and that was the Kentucky State Medical Association. For the last ten years I have been doing penance and fasting in the hope that I might some day be privileged to stand in the class of the members of the Kentucky State Medical Association. (Applause). That accounts for some of the pleasures and joy I have been having with you to-day. It is a pleasure to come here and see you and be with you and be made one of you, as you have so generously made me one of you in the capacity of Secretary of the American Medical Association, and if you secretaries of county medical societies have your troubles, you know something of the troubles that Dr. McCormack has had as secretary of the State Medical Association. I trust you will be a little more lenient with me as I have heard that there are troubles in connection with the office of secretary of the American Medical Association, but the county medical societies can materially help the American Medical Association. There are a great many things that we have in common. There is one thing I have learned in the few months I have been in the secretary's office in the American Medical Association, and that is, there is great need for coordinating our efforts. The time was when there were only a few inhabitants in a district, and the average medical society was not sufficiently large for its doings to attract the neighbors, and then, after a while, some man moved in and it became necessary to draw the line; that he should give up certain things. We felt bound by individual rights to the other fellow and demanded that the other fellow should give up something for our comfort, and so a community of interests was established. And then another one came and the matter became still more complex, so that to-day when you and I get up from our beds in the morning and turn on the electric light or gas light, we have used

the labor of a number of different individuals. When we go to our bath there is another group of men to whom we are indebted. When we go to breakfast still another complex relationship is entered into, and so throughout the day we find ourselves in a civic sense having an interchange of relationships, giving up certain things that belong to us under the extreme idea of personal rights for the advantage that comes to us from what we call civilization. It seems to me, we are in exactly the same position as physicians. When the country was so large that one doctor was either fifty or one hundred miles from another physician, he had to do the best he could. He may have been considered the best doctor in his community, but to-day, with a group of physicians coming into every community it is necessary to help the other fellow, and it is very essential for the other fellow to be helped. This other fellow is to be helped and we are helped by him to the best advantage at the present time by the advantages of the county medical society. The county medical society is in a peculiar condition. It is a body that treats of scientific subjects; at the same time, it undertakes to solve social and economic problems, both society affairs and the affairs of individuals. In order that these societies may live in harmony one with the other, being divided by a real or imaginary line, it is necessary for us to have a state organization to which these societies can send delegates to the business body without the advantage of taking a very active part in the scientific work, but nevertheless helping the scientific session. Every member of the county society is privileged to attend scientific sessions, in order that the state, divided by imaginary lines many times, shall be co-ordinated and held together. The national association comes in to which the state societies send to the business body delegates and, at the same time, the business meeting is being held the scientific work of the various sections is going on. Every county medical society has a great interest in the state society and an interest in the national association, and it is the feeling of many of us that this interest should be accentuated and acknowledged and emphasized, but in order that the American Medical Association may carry on its work it is necessary to maintain a keen interest in the scientific work. But this is too large a problem to enter upon to-night.

With reference to the problems of the secretary and the secretaryship, I want to say to you, the secretary of every organization can do effective work only in proportion as he is supported by the constituents of the various societies of which his organization is composed. It is very much like the old, old story, when Israel was in bondage. They fought with the opposing forces, and so long as the hand of Moses was raised toward heaven everything seemed to be all right, but the minute Moses' hand dropped the battle

turned against them. And so as Aaron and Hur supported the hands of Moses, it is necessary for you to support the hands of the secretary. The secretary cannot fight the battle alone because his physical force must give out, but if you put the spirit of Aaron and Hur into the secretary's work, the county medical society will be what you want it to be, and in turn the Kentucky State Medical Association what it ought to be. We find that all secretaries have troubles, and we will be happy indeed to hear from anyone who has solved the riddle of life somewhat after the fashion of this little jingle:

"There's a little secret,
Worth its weight in gold,
Easy to remember,
Easy to be told.

"Changing into blessing
Every curse we meet,
Turning hell to heaven,
It is this—keep sweet."

REPORT OF COMMITTEE ON WORK TO BE UNDERTAKEN BY COUNTY SECRETARIES DURING THE COMING YEAR.

G. E. Gianinni presented the following report:

The medical profession should be the leaders in every community on matters of health. The county medical society is the organized representative of the profession. Its duty is to teach the public correct views on public health. Our relation to the public should be such as will inspire confidence.

For report on work to be undertaken by county secretaries during the coming year, your committee submits the following:

1st. Get out a printed annual program. This program should have on it every doctor in the county. Put on four essayists for papers, two of whom you can depend on to be present and have their papers read.

2nd. Have regular meeting dates and places; meet at least once each month. For notices of these meetings mail a program to each doctor at least three days before each meeting.

3rd. Plan for a substantial social side of the profession; have a smoker, barbeque, or a dinner, etc.

4th. Take the public into your confidence; have open meetings; invite the public to attend. Have joint meetings with teachers, ministers, lawyers and druggists; discuss medico public questions; and put them on the program; as expert testimony for a lawyer; the moral influence of the doctor for a minister; medical inspection of the schools for a teacher; or patent medicines or national formula to be discussed by a druggist.

5th. Meet with the Anti-Tuberculosis Society some Sunday at church. If you haven't any Anti-Tuberculosis Society, organize one; you need it.

6th. Special notice to the doctors before each meeting; the day of the meeting call each one by phone, or send one by for another one and insist on his coming.

7th. Make it plain to every doctor that it pays to attend his medical society, for he needs the society and the society needs him.

8th. Have a Medical Education Committee appointed by the society whose duty shall be to occasionally have printed in local newspapers articles on tuberculosis, public hygiene, and other subjects of general interest.

9th. When a paper is read before your society that will be of interest to the public have it published in the local papers.

10th. Secure all the good papers for the JOURNAL and some that are not so good, for it will encourage the writers to do better next time.

11th. Report your meeting to the JOURNAL promptly for publication. It will help very materially to keep up interest in your society, if your members read in the JOURNAL what they have said in the society.

12th. Get every eligible doctor in your county to join the society and pay his dues promptly; this has been done in some counties and can be done in all.

13th. Each and every secretary should strive to make his society the best in the State. The foregoing are only suggestions of what may be done. The secretary should have a creative mind and add to or take from these suggestions as will meet his local needs.

Respectfully submitted,

B. E. GIANNINI
Chairman.

A. T. McCORMACK,
Committee.

On motion of Dr. McCormack, the report was adopted.

The following officers were nominated and elected: President, T. A. Frazer, Marion; Vice President, Vernon Blythe, Paducah; Secretary, L. H. South, Bowling Green.

Adjourned.

Adenosarcoma of Left Kidney in a Child.—Pederse presents the history of a case of adenosarcoma of the left kidney occurring in a child of three years, previously healthy. The important points in this history were the appearance of copious hemorrhages from the bladder and of pain in the left side. It was found that the urine escaped from only one ureter. Operation for removal of the kidney showed that it was an adenosarcoma. The child recovered.

ORIGINAL ARTICLES

PRACTICAL LESSONS FROM EIGHT MONTHS OPERATION OF OUR VITAL STATISTICS LAW.*

By W. L. HEIZER, Bowling Green.

STATE REGISTRAR OF VITAL STATISTICS.

Twelve months ago the Vital Statistics Law existed only on paper. Within sixty days there had sprung up, as in a night, an army of thirteen hundred local registrars chosen by the physicians of the State. A personal visit to about fifty counties in every section of the State, hundreds of letters from local registrars, prompt monthly reports from every county of the State, convince us that no more capable body of officers could have been selected. In this period competent men had been chosen to serve the interests of the State at a small compensation, their commission and supplies forwarded, and on the first day of January 1911, the Vital Statistics Law began its operation without a hitch.

The apparent ease with which this enormous task was accomplished is explained only by the fact that Kentucky has the best Medical organization in the United States.

The undertakers of the State upon whom, perhaps, is worked the greatest hardship in securing data and a burial permit, generously endorsed the law, and at their annual meeting of undertakers and embalmers in Louisville, May, 1911, passed unanimously a resolution setting forth the value of the law, and pledged their united and individual support in the present health campaign of the State Board of Health.

The physicians of Kentucky, following their habit of cooperation in doing good things, took hold and pushed hard and all together, thus, overcoming the first storm of protest that always comes when establishing a new order of things.

There is no question but that the present satisfaction and pride that the people of the State as a whole now manifest toward their law is a result solely of the missionary work done by the medical profession of the State in explaining to them its worth and relation to their material and physical welfare.

Forty thousand two hundred and fifteen births and 20,821 deaths have been reported. The relative causes of deaths from communicable diseases, deaths from cancer and violence makes an interesting picture. Tuberculosis is responsible for 18 per cent. of all deaths the average of registration states being 11 1-2 per cent. Thus, is clearly pointed

out, by official records, the greatest fight the people of Kentucky must make. Pneumonia follows with 8 1-2 per cent; violence 4 1-2 per cent; diarrhoea and enteritis (under 2 years) 4 per cent; cancer 3 per cent; typhoid 3 per cent; meningitis 3 per cent; influenza 2 per cent; measles 2 per cent; whooping cough 1.4 per cent; diphtheria and croup .8 of 1 per cent; puerperal septicemia, .5 of 1 per cent; and scarlet fever 1-100 of 1 per cent of all deaths.

It is an old saying that statistics is a great deal like butter. They depend upon who makes them. And so it is. The medical profession of Kentucky has undertaken the task of making statistics for the State. They have made an enviable start and they have entered not for a day or year, the warfare against preventable diseases. They realize that Vital Statistics are as inseparable and indispensable for consistent, intelligent health work as book-keeping for a bank. They know, too, that incomplete statistics are worthless as they tell false tales; therefore, it is the duty devolving upon them to insist that every death that occurs in a community shall be properly recorded. The unfortunate few who are callous to human suffering, indifferent to progress, ignorant of the altruistic in their profession, we always have with us. And, occasionally, we hear of a man said to be a doctor who refuses to comply with the law and make returns of births and occasionally deaths. They fortunately are rare, and a recent summary of the accounts of physicians, with whom we keep an open account of every one in the State, shows that such a man belonging to the Kentucky Medical Association is the exception. It is unfortunate that we are not permitted to allow such a one to follow in peace his perverse, selfish way. Such a line of conduct, however, vitiates the Vital Statistics of his community or county and affects the State record, may deprive the widow or children of property or social privileges, prevent the prompt location of an epidemic, and is a violation of law; and it is the unpleasant duty of the medical profession to insist that all such violations be brought to the attention of the proper authorities. Recent accounting with all the doctors of the State shows that 95 per cent. of them are reporting promptly their births and deaths.

Probably one of the most important features in making a death record is to state accurately the cause of death. Industrial insurance policies of some of the companies, which contain limitations of payment when death is due to tuberculosis, are responsible for some suppressions as to the cause of death from this disease in order that the physician's bill may be paid. Of course, this is a problem of downright honesty or dishonesty of the

*Read before the Kentucky State Medical Association, Paducah.

physician and this paper cannot or will not change a man's moral nature. Again it has been found that a physician is fearful of his reputation as a typhoid fever doctor if he makes a return of death from plain typhoid, and states a more deadly disease. Again, we are unable to change the "leopard's spots" or supply courage where that quality is lacking. The real problem is yet before us. What the people of the State want is not to be told of the loss of their family and friends, as shown by the death records of the Bureau of Vital Statistics; they have already a record of such events written in disappointed, heart-broken lives, and the newly-made graves of their dead. They want and demand relief at the time of their affliction and before death lays his hand upon their loved ones.

This means that that part of our law requiring the report of morbidity statistics be put in operation at the earliest possible moment. This has been deemed inadvisable as yet, until we are accustomed to the new order of things in reporting our births and deaths. As soon as our machinery has been thoroughly tried out, is in good working order, the added task of reporting communicable diseases will be undertaken; and it is then and not until then, that prompt life-saving work will be done most effectually, and we will have vital statistics in contradistinction to devitalized statistics with which we are all so familiar.

In the meantime we have urged our local registrars, Health Officers, and the medical profession to report promptly epidemics that active steps may be taken at once.

As a practical example of what Vital Statistics mean to the people the epidemic of typhoid at Paintsville is mentioned. This fact was reported at the time of their distress and an immediate investigation was made. The focus of infection was found, from which twenty-five cases had developed, resulting in three deaths. The excreta from the first case were thrown upon the ground within ten feet of a mule shed in which were breeding thousands of flies. By them the disease was carried into the unscreened homes and later the water supply below was infected. A meeting of the public was called, fully 500 being present, a public health talk was given, their disease explained to them and the means of its spread and prevention. The County Board of Health met with the most influential citizens of the town and appropriated enough money to haul away filth, remove the numerous pig pens, screen houses, provide lime and containers for bowel and kidney discharges. These measures were faithfully carried out by the County Health Officer, Dr. Daniel, and within ten days the epidemic was under control.

Again at Sandy Hook there occurred an epidemic of typhoid fever with twenty cases and two deaths. An investigation revealed an infected water supply by means of open top wells and the bucket-on-rope method of drawing water. In one instance there were five ill in one family and the well was located under the same roof. An attendant from the sick room drew a bucket of water and used the fingers to release the valve at the bottom of the bucket, permitting the water to flow over the hand into the bucket.

Similar action was followed, as in Johnson county, almost the entire population attending the public meeting. The county liberally voted enough money to clean up, screen houses, and set the example by installing a pump properly fitted to a new concrete top extending down the wall of the well for a distance of four feet. Under the direction of Dr. Lyons, county health officer, the epidemic was checked almost immediately.

This is our conception of what Vital Statistics really mean and the only way the people can know or will know what can be done in the way of preventing disease.

We have been able to learn of the prevalence of hookworm disease in many counties of the State. In several instances we have had the pleasure of addressing audiences in which there have been from one to four hundred school children. When asked to raise their hands if any had ever suffered from "dew itch" or "ground itch," a survey of the large per cent of children who responded showed, conclusively, that hookworm was prevalent in those communities. This again is what we believe Vital Statistics to mean. Our records of deaths and reports from physicians and health officers resulted in the calling of the pellagra conference at Corbin, one of the most remarkable gatherings it has been my privilege to attend. At that time about one hundred and forty cases were reported, symptoms and treatment discussed, and efforts instituted to study its etiology.

Covington and vicinity is now having an epidemic of anterior-polio-myelitis. We have just finished an epidemiologic and clinical study of twenty-six cases*, and while no new facts as to its etiology have been discovered, much that will be of value to the profession, hence to the people of the State, will be published soon in the bulletin of the State Board of Health. These are illustrations of what we are endeavoring to do to make Vital Statistics of real value to the people for whom and upon whom the labors of the medical profession and its executive staff, the State Board of Health, are expended.

With this aim in view, we propose to pub-

*This number is increased to 45 December 1, 1911.

lish in the monthly bulletin articles written especially for the public. They will be told how diseases are spread, prevented, and controlled, their prevalence and the importance of complete reports of births, sickness and deaths. The bulletin will be mailed to every school teacher in the State for whom special articles will be written for use in the school room; every minister in the State, doctor, local registrar, undertaker, State and county officer, newspaper editor, and to every member of the Woman's Clubs of the State. A number of teachers' institutes have been visited, and it is part of the plan to visit every teachers' institute in Kentucky. By this means of cooperation, it is hoped that there will be taught, to-day, what yesterday we did not know about the prevention of diseases and preservation of health, that, to-morrow, the people of Kentucky may live longer, happier, and freer from disease, and be able to carry on the warfare against preventable diseases with less opposition from the ignorant who must be protected in spite of themselves.

We believe that by proper cooperation of these forces, we can add, within one generation, a few years to the average of human life in Kentucky and make it plainly apparent to enough people that it is an economic proposition in the saving of unnecessary drug, undertaker, nurse and doctors' bills, to provide more money for a greater scope of work and employ in each county of the State a specially trained health officer, at a living salary, to prevent the spread of communicable diseases.

DISCUSSION.

J. N. McCormack, Bowling Green: As some of you know, I have been out of the State for the last three months, and while Dr. Heizer's work is being conducted under the superintendency of the State Board many of the figures he has presented this afternoon are a revelation to me. I know the scope of his work, and I know his fitness to discharge the duties which have been assigned to him. I knew the spirit with which his work would be received by the undertakers because I had attended their state meeting; but the unanimity with which the work has been undertaken by the profession, by the local registrars, and by the undertakers has been a surprise to me. Nothing like it has occurred in any state in the Union. I was assured by Dr. Wilbur that it would be useless for us to attempt to collect births in Kentucky until we educated the profession by collecting the deaths for about ten years. He said it could not be done in any state in the Union. We have gotten nearly all births for almost every county in the State of Kentucky for nine months. I would like at this point to pay my tribute to the doctors of Kentucky, and espe-

ally the doctors in the country districts who have taken up this work in such a fine spirit, and then pay my tribute to the undertakers of the state who have unselfishly, and without compensation, volunteered to do this great work for our people. With such a work and spirit it is only a question of time when we know we will have every case of sickness that occurs and every death reported in this state, and what causes the death and be able to institute a course of study as to the cause of particular epidemics.

Dr. Heizer's modesty prevented him from saying that he was sent to Painsville as a result of death reports which came in through the agency of the State Board, to make an investigation of an endemic of typhoid fever and to undertake preventive work. He did the same thing at Sandy Hook. I am glad for you to know that. It is in this practical spirit this work is being conducted. In the same way the board has undertaken the survey of the water supplies of the State of Kentucky. We expect to take two or three years to do this; we expect to have maps of the entire water supply of this state and the sources of pollution in every locality if we can continue to have the united support of the members of the profession of Kentucky, as we have had in the past. We know that excellent work is being done in the State Bacteriological Laboratory, no better done in any other state in the Union. In this connection I would like to say, I had a letter yesterday from the director of the Rockefeller Sanitary Commission, saying they were just ready to take up the hookworm work in a voluntary way; that they have salaried officers appointed in nearly every state of the Union, and he said that nothing had been presented to the hookworm convention equal to that of our State Bacteriologist at the meeting held in Nashville. So, while we are in the infancy of this work, the kind of support we are going to have from the doctors in every community in Kentucky will enable us to do almost ideal work in this state in the next four or five years, and it gives me great pleasure to commend the efforts of my young friend, Dr. Heizer, whose work has been so able and so efficient, although we are hardly paying him a salary sufficient to support his family. But we are going to correct that some of these days. I want to commend him to you, and ask that you return to your respective county societies, call a meeting of the undertakers and local registrars and doctors, and take up all this work in each county in the state in the kind of way that the benefits of modern sanitary science can be brought to every hearthstone in the State of Kentucky. (Applause).

T. A. Frazer, Marion: The only thing I regret is that there were so few present to hear the excellent paper that was presented by Dr. Heizer. It depends upon the doctors to make these laws popular. I have not heard of a doctor who belongs to this association objecting to the

Vital Statistics Law. Dr. Heizer has labored faithfully in this work. He has written thousands of letters; he has called hundreds of doctors up over the telephone. He has labored day and night, and I want to compliment him on the work he has done. In this connection I want to say that whenever a politician sticks his head up for the position of representative or senator in any district of the State, the doctors ought to demand of him how he stands on these vital questions, and I want to say to you, no man can ever get my vote who is opposed to the work that is being done by the State Board of Health and by Dr. Heizer. No man can ever get my vote who is ready and willing to vote against the lives of the women and babies of the State of Kentucky. There is no music so sweet to the ear of man as the prattle of a healthy, happy baby, and let us as doctors do our duty. Let us as doctors stand by the right and tell the people that this is a labor of love for them and not for ourselves; that we are not looking for glory nor for honor, but that we are looking to the welfare of men and women, of the boys and girls of Kentucky. Let us tell the people we think more of the boys and girls of Kentucky than the politicians and all of the filthy dollars that ever went into anybody's pocket. Let us tell the people that we are doing this work for them and not for ourselves; that we are trying to protect the mothers and babies; that we are trying to save them from untimely deaths, from some preventable disease; that we are trying to snatch them, as it were, like a brand from a burning flame, and that we are in earnest about this work, that our heart is in this work, and that we expect to keep it up in spite of any opposition that may come from any source under the shining sun.

W. L. Heizer, (Closing the discussion): I simply want to take this opportunity of thanking the physicians through our official organ, The Kentucky Medical Journal, for their united and hearty support they have given us in this campaign. We fully realize that without the support of the physicians of the State we would be helpless and powerless, and I also desire to thank the speakers for their kind remarks.

TYPHOID FEVER AS SEEN AND TREATED BY THE COUNTRY PRACTITIONER.*

By V. A. STILLEY, Benton.

According to Osler and all of the best authorities, typhoid or enteric fever is a general infection caused by bacillus typhosus, characterized anatomically by hyperplasia and ulceration of the lymph follicles of the intestines, swelling of the mesenteric glands and spleen, parenchymatous changes in other or-

gans. While these lesions are almost constant, there are cases in which the local changes are slight or absent, and there are others with intense localization of the poison in the lungs, spleen, kidneys, or cerebro-spinal system. Clinically the disease is marked by fever, rose colored eruption, diarrhoea, abdominal tenderness, tympanitis, and enlargement of the spleen. These symptoms are inconstant as you all know the fever varies in its character. I think it hardly necessary to go into the history of typhoid fever except to say, that in 1818 Pierre Breteanu, and in 1829 Lewis, gave it the name of typhoid. Typhoid bacillus was first discovered by Koch and Eberth and first cultivated by Gaffky in 1884. Typhoid bacilli has a remarkable resistance. In sterilized water it retains life for sometime up to three months or more, and it shows at first slight increase. In water that is not sterilized it perishes in about fourteen days on account of the water bacteria, this occurring more rapidly in flowing than in still water. Under favorable circumstances, protected from light, drying, and other forms of bacteria the typhoid bacillus retains its property of life for a very long time. So in milk that has been experimentally contaminated, for thirty-five days, bacilli which were living, showed properties of development. In the superficial layers of the earth they have been shown to be alive after five and one-half months. In mud taken from rivers and wells this condition was noted for three months. Dried in thin layers of earth they remain alive from twenty to thirty days. Dried in various articles of clothing from one to two months. (Uffelman). They remain in feces three months at the longest, provided however, that there are not present simultaneously many bacteria which produce decomposition. In the dead body they also appear to remain alive a long time. (Losner). They bear cold well. Alternate freezing and thawing does not injure them. They are less resistant to heat. The germ enters the body through the digestive tract, and produces characteristic ulcers in Peyer's patches and solitary follicles of the small intestines. From these the bacilli make their way to other parts of the body especially the spleen, liver, kidney, gall bladder and mesenteric lymph glands. The bacilli are found in the intestinal ulcers, the mesenteric lymph glands, spleen, liver and occasionally in the gall bladder. They are eliminated by the feces and sometimes by the urine. Ages that are most frequently attacked are from fifteen to thirty years. Not any special difference as regards sex.

PRODROMINAL STAGES.

Headache, pain in limbs and back, characteristic temperature curve (though not al-

*Read before the Kentucky State Medical Association, Paducah.

ways present) showing general rise with daily remission, spleen enlargement, pea soup stools, dicrotic pulse, rose spots, etc. I am merely detailing the symptoms of an ordinary case of typhoid fever, as all of you with experience know that each case is a rule unto itself as to the most predominating symptoms, for very few cases in my experience have all the symptoms of a typical case. The eruption is a discrete, slightly raised, hypereamic macules, so-called rose spots or roseolae, varying in size from a pin head to a pea and disappearing on pressure. The spots appear about the beginning of the second week chiefly on the abdomen, also on the lower chest, back, and thighs. They recur in crops throughout the second, third, and fourth weeks. To differentiate typhoid from malarial fever in our country is very difficult. In a great many cases the clinical course and the temperature curve may be quite similar in the two diseases, and it is only after eliminating malaria that you can diagnose typhoid. We can have recourse to the use of the Widal test, and thanks to our very efficient State Board of Health, we can have our doubtful cases examined by a competent bacteriologist for the asking, and to my mind this is one of the greatest strides we have made in Kentucky for years. For preventive medicine and knowing how to treat and diagnose disease is for medical men. The complications are many in typhoid fever: Pneumonia, meningitis, constipation, nephritis, diarrhoea, perforation, peritonitis, etc. Perforation occurs toward the end of the second week or during the third week, or again in one case of my experience perforation occurred eleven days after temperature became normal.

Hemorrhage occurs from the twelfth to the twenty-fifth day. If you have continued hyperpyrexia you may have meningitis.

SANITARY PRECAUTIONS.

The stools, urine, vomit, and sputum, and the towels, napkins, bed-linen, and clothing should be disinfected, which most of us fail to do in the country practice, for it is almost impossible to have your instructions carried out.

PROPHYLAXIS.

Good water not contaminated, avoidance of uncooked food that has been exposed to infection, disinfection of all materials, feces, sputa, bed-linen, clothes, etc., as stated above. A case in point that has not been reported to the journals of the contamination of typhoid fever occurred in an adjoining county. A party of thirty-eight were gathered at a quilting. During the day there was quite a hard rain. The water in the well became muddy from surface drainage, and in three weeks there were twenty-five cases of typhoid fever

of those who were present. There had been typhoid fever in that house some months before, and the analysis of the water showed typhoid bacilli in abundance, which proves the more conclusively the absolute necessity of looking into our water supply and the disinfection of stools, etc., for every case of typhoid fever is dangerous to the county without this precaution, and for every case of typhoid there is a source of infection. Vaccination against typhoid fever is due to a French physician, but the French government did not adopt it for the protection of its own soldiers until after this method had received thorough and successful trial in the armies of both the United States and Great Britain. In the British army, especially in the colonies, it is now as much used as vaccination against smallpox. In the United States army there are only one-sixth as many cases of typhoid as before this method was adopted. It's worth was convincingly shown during the recent massing of troops on the Mexican border; and I see from reports that the Surgeon General of the Army and several members of his staff propose to subject themselves to vaccination against typhoid fever, so great is their faith.

Treatment of typhoid fever is purely symptomatic. There being no specific, I begin treatment by cleaning out the alimentary canal. Calomel being preferable to me on account of the chologogic and disinfecting effects. Use salol, digitalis, bismuth, phenacetine as the indications arrive, and as for antipyretics, to my mind there is less shock to use them (well guarded) in most cases than the Brand method of hydrotherapy or any other method of hydrotherapy except sponging, as it is entirely impossible in the majority of cases of the country doctor's practice. Very few of our patients have a bath tub and a great many of them never saw one. Diarrhoea should be treated by bismuth, calomel, and opium. Keep the bowels open.

HEMORRHAGE.

Ice, morphine, sulfuric acid, ergot, and any other complication in the course of the disease, of course, should be met. Disinfection of stools by lime is best, and of urine and bed-clothes by carbolic acid. The patient should be kept as quiet and clean internally and externally as is possible under the circumstances, looking always for any untoward symptoms. The diet should be nutritious liquids. Milk is my preference, of course varying with other liquids. But after all the prevention of typhoid fever is our greatest duty.

TYPHOID FEVER—STATISTICS AND PROPHYLAXIS.*

By PAUL HANSEN, Bowling Green.

STATE SANITARY ENGINEER OF KENTUCKY.

Previous to 1905 there was an average death rate from typhoid fever within the vital statistics registration area of the United States of 32.2 per 100,000. Since then there has been a steady decrease until in 1909 the death rate was reduced to 22 per 100,000, or double what it is at the present time in most European countries. The death rate in this country is not nearly as great as the death rate from two other preventable diseases, namely: that from tuberculosis which is about 7 1-2 times as great, and that from pneumonia which is about 6 1-2 times as great. In its fatality typhoid is about on a par with diphtheria and croup (death rate 21.2 per 100,000) and bronchitis (death rate 24.9 per 100,000) while it claims about double as many lives as do measles (death rate 10 per 100,000) scarlet fever (death rate 11.9 per 100,000), and influenza (death rate 13.6 per 100,000).

Notwithstanding these relative figures the prevention of typhoid fever is generally regarded as second in importance only to the prevention of tuberculosis, and rightly so for many reasons, the chief of which may be stated as follows:

While typhoid has a lower death rate than tuberculosis or pneumonia the percentage of fatal cases is much lower thus producing a morbidity rate which is nearly as great as that for pneumonia.

Typhoid is, comparatively speaking, a readily preventable disease and there is little if any more excuse for its existence than there is for the existence of Asiatic cholera, and it goes without saying that where the remedy is evident and can be applied no time should be lost in making the application.

The means used to wipe out typhoid fever are also a great protection against infection by other diseases—for example, it has been conservatively estimated that purification of public water supplies will save 3 or 4 lives from deaths due to other causes for every life saved from death due to typhoid fever.

Typhoid fever is essentially a filth disease, for infection by the typhoid bacillus implies that one has swallowed fecal dejecta coming from some other person and though this fact is not always visibly evident the mere suggestion is sufficient to raise a vigorous demand for sanitary improvements.

Finally, it is to be noted that in the United States the total number of deaths from ty-

phoid amounts to about 20,000 per annum, the number of cases of sickness not resulting in death amount to about 180,000 per annum, and the financial loss no doubt reaches the stupendous total of \$100,000,000 besides which the cost of preventive measures dwindles into insignificance. To this it may be added that according to a very conservative estimate made by Dr. J. N. McCormack on the basis of voluntary statistics sent in by physicians, the financial loss from typhoid to Kentucky is about \$5,000,000 per annum.

Dr. W. L. Heizer, State Registrar of Vital Statistics, has furnished some interesting mortality figures for typhoid fever in Kentucky during the present year, from which it would appear that from January to August inclusive, deaths from this disease occurred at the rate of 25 per 100,000 population per annum, thus showing that Kentucky has more than the average amount of typhoid fever found in the other registration states. The statistics are further arranged by Dr. Heizer to show death rates by county groups designated as the eastern or mountain group, the Ohio River group including all the counties bordering the Ohio River, and the intermediary group including the main portion of the blue grass region and the remainder of the State. The mountain group shows a death rate of 26.1 per 100,000, the Ohio River group shows a death rate of 20.2, and the intermediary group shows a death rate of 28.1. The low figures for the counties bordering along the polluted Ohio is rather interesting as indicating the protection which the purified water supplies of the large cities afford against typhoid infection. The other two figures are high and are probably due to unsanitary conditions both urban and rural.

At the risk of repeating something that is already well known among the physicians of the State, a brief review will be given of the accepted facts relative to the character of the typhoid bacillus and modes of typhoid infection. Without these facts clearly in mind the value of certain prophylactic methods cannot be properly appreciated.

By a strong chain of evidence, mostly circumstantial, the bacillus discovered by Eberth in 1880 is now known to be the cause of typhoid fever. It is a rod shaped non-spore forming organism with rounded ends and from 0.001 mm. to 0.004 mm. in length. It is provided with a number of flagella which give the germ a lively motion in liquid media. But very little is known of the inner structure or the precise conditions which affect its behavior inside or outside the human body.

There are, however, a few things concerning the germ that are known and which fortunately furnish the key to positive prophylactic methods. To begin with, we know that

*Read before the Kentucky State Medical Association, Paducah.

when typhoid invades the human body enormous numbers of the bacilli, counted in billions during a single day, are discharged with the urine and feces being specially abundant during the earlier stages of the disease. The length of time that the germs continue to appear in the bowel and bladder discharges is variable and may be from a few weeks to many years. Persons who carry the germs for great periods of time are designated as typhoid carriers, and there are instances of such carriers who have never actually succumbed to the germs' attack. Occasionally the nose and throat are found to contain the bacillus, especially when pneumonic symptoms are present, and thus sputum discharges become infected. Much more rarely the germs are found in the perspiration, and of course sores on the body may be a source of infection.

Outside the human body the typhoid bacillus generally finds an unfavorable environment and dies out rapidly. There is, however, a resistant minority, numerically great, however, which may persist in virulent form for long periods of time, many weeks or even months. Exact knowledge as to the longevity of the typhoid bacillus outside the human body is very meagre. Laboratory experiments would indicate that the most resistant forms may persist in moist fecal matter for months or even years, in water at ordinary temperature for about three weeks, in ice about two weeks, in water at boiling temperature not over five minutes, in fresh milk indefinitely, but in some milk they are very short lived, and dried in sun light not over ten minutes. It is indeed fortunate that the typhoid bacillus is thus nonresistant for otherwise it would be the greatest scourge of the human race.

From this general summary it is evident that aerial and fomite infection by typhoid fever are negligible quantities, but an indiscriminate disposal of bowel and bladder discharges, especially the latter, an ineffectual manner of handling these discharges, or carelessness in touching the patient may result in the infection of the healthy through contact, through the medium of flies and possibly other insects of filthy habits or through the contamination of drinking water, milk, shellfish, vegetables and fruits, eaten raw, and no doubt also by some means not now recognized.

Plainly all typhoid infection by the means above enumerated could be effectually stopped; first, by thorough disinfection of all discharges at the patient's bedside and by continuing such disinfection until the typhoid germs have entirely disappeared from the feces and urine, and second, by unusual precautions on the part of attendants and the convalescing patient to prevent contact in-

fection through the medium of soiled hands, utensils, dishes, soiled linen and clothing. This line of defense against the spread of the typhoid germ in the very nature of the case cannot be made perfect because of frequent ignorance and stupidity on the part of patient and family, failure to discover the case in its early stages, failure to make an early diagnosis and the impracticability in most cases of examining analytically the discharges of convalescents. But it can be made far more effective than it is at present and it is highly important that it should be made more effective, especially in small towns and rural districts where the old fashioned privy, cesspool, and the shallow well abound. Disinfection of discharges and precautions against contact infection can be rendered an effective barrier against the spread of typhoid fever only through the activity of the family physician in instructing his people in the character of the disease and the precautions which must be taken against its spread. When, as often happens, the patient and the patient's family are ignorant or stupid the physician will confer a public service by making some arrangements for treatment in a hospital when available, or by providing trained nurses. In these matters the public health and public service authorities alone are almost powerless; cooperation of the family physician is absolutely essential.

Once the typhoid bacteria have passed the barrier formed by the immediate control of the patient's discharge at the bedside, infection of other persons is certain to occur in many instances; but there is much in the way of providing secondary barriers that the public health and public service authorities can do, should do, and should be provided with means for doing. It is the purpose of the writer to discuss the character of some of these secondary barriers in the following.

With increase in the size of cities pure water supplies are no longer obtainable from springs and wells, with the result that they must be taken from large surface streams. With increase in the density of rural populations and increase in the number of the smaller communities the surface streams inevitably become so polluted that they are unsafe as sources of domestic water supplies. Because of the fact that water is a prime necessity of life and is used by everyone it has been the universal experience of communities which have sewage polluted water supplies to have an abnormally high death rate from typhoid fever, and occasionally, such communities are visited with great epidemics. Purification of public water supplies can now be effectively and economically brought about by methods well known to sanitary engineers, and there is no one thing that is so effective,

in checking the ravages of typhoid fever, as well as other less definitely defined water-born diseases, as purification of public water supplies. The cost of purification under the most unfavorable conditions rarely exceeds \$3.00 per capita for original construction and often is less than half this amount. The cost of operation does not exceed 20 cents per capita per annum. Such sums as these are so insignificant when compared with the value of the great number of lives that may be saved that there no longer remains any excuse for any community not having purification unless its public water supply is well above suspicion.

The inevitableness of more or less stream pollution has already been referred to but there is no excuse for our streams, which should be available as public water supplies, becoming so contaminated as to place an unreasonable and unsafe burden upon water purification works. As in the case of the design and construction of water purification works, sanitary engineers are now in possession of sufficient knowledge and experience to enable them to design and construct treatment works for sewage and industrial wastes that will meet nearly any local situation likely to be encountered. The conservation of a reasonable purity of the waters of our streams cannot be undertaken any too soon and some central state authority such as the State Board of Health should be given ample means both legal and financial to carry on an effective regulation of this important matter.

Next in importance to the protection and purification of our public water supply is the control of milk supplies. Some means should be found for frequently inspecting every dairy in the State where milk is produced for public sale, and samples of the milk as delivered to the consumers should be frequently analyzed. Whether this work is done by the State, the municipalities, or a combination of the two makes no material difference, but it is of prime importance that it be done thoroughly and that dairymen producing unclean milk be dealt with promptly and fearlessly.

In every community the local health authorities should be specifically directed by ordinance to abolish all private wells where a public water supply of assured good quality is available unless it can be definitely shown that the construction of the well and the peculiarities of the geological formation penetrated absolutely preclude the possibility of the water being influenced by surface conditions. In built up communities soil pollution on an extensive scale is unavoidable and contamination of ground water is bound to follow.

In the light of the now well known filthy ways of the house fly, the danger of an ag-

gregation of outdoor privies and other accumulations of filth must be at once apparent and it is quite as important as in the matter of private wells that the health authorities should be specifically instructed by ordinance to abolish all privies where public sewers are available; and where sewers are not available the ordinance should prescribe a type of privy that will effectually prevent access of flies to the fecal matter and provide for frequent inspection in order to enforce the maintenance of such privies in a proper state of repair and cleanliness. Accumulations of garbage and stable manure should not be tolerated in densely inhabited districts, and wherever possible municipal free collection should be provided.

Finally there should be maintained an inspection of foods likely to be eaten raw such as shellfish, berries, celery, other vegetables and fruit, to make certain that neither in the growth or the handling of such foods is there a chance for dangerous contamination. Such food inspection is quite as important as meat inspection regarding which we hear so much. The fact that meat is rarely eaten raw removes from it the danger that attends the consumption of raw foods.

By way of brief summary it is desired to state that the death rate from typhoid in this country in general and in Kentucky in particular is far too high, and moreover a high death rate is especially prevalent in rural districts where unhealthful conditions seem least excusable.

The first line of defense, and in the rural districts the only line of defense, against the spread of this dread disease must be maintained by the physicians through careful and painstaking instructions to their people and, in cases where ignorance must be dealt with, through the utilization of hospitals or at any rate through competent trained nursing.

Inasmuch as the first line of defense is a long and thin one and inasmuch as it is constantly being attacked at all points it is not to be wondered at that it is often broken through. The second line of defense must then be held by the officials in charge of public health and public utilities; and as the second line of defense is also the last line of defense it should be made as impregnable as possible and no gap or defile should remain exposed. To this end our water supplies must be made safe beyond peradventure of doubt; our streams must be protected against undue contamination; our milk supplies must be subjected to rigorous control; polluted wells must be filled in; outdoor privies must be abolished wherever possible and where this is not possible they must be well constructed and carefully supervised; there must be inspection of foods eaten raw; and to prevent the breeding

of flies accumulations of manure and filth must not be permitted.

Typhoid is a filth disease and to stop having typhoid we must stop swallowing human dejecta.

DISCUSSION.

W. F. Boggess, Louisville: However trite a discussion on typhoid fever may seem, it is always a question of such vital importance to the physician and laity that it should never become trite, and if we should have a symposium on typhoid fever at every annual meeting of our State Medical Society, the time spent in listening to that symposium would not be in vain.

The subject of typhoid fever is one that is not only vital, but it is as yet an unwritten book. I dislike very much to hear the term self-limited used in any disease, and in no disease is the term so misleading as in typhoid fever. To say that the treatment of typhoid fever consists entirely of proper feeding is not true, nor is it scientific. There is much in the prevention of complications in typhoid fever from treatment. There is much in the medical treatment of typhoid fever just as there is in other infectious diseases, and while some men claim that they get just as good results from the withdrawal of all medicaments and simply administer water and no food, another practitioner of repute will say that he can abort every case of typhoid fever within ten days by injecting first one grain of bichloride of mercury, and a half a grain the second day, and a third or a tenth of a grain of bichloride of mercury on other days. We have all these fads and foibles to contend with.

As to the etiology and pathology of the disease, in every case of typhoid fever we have an infectious disease of a dangerous character, and there is no such thing as a mild case of typhoid fever. You have a disease that has got to be watched from beginning to end; you have a disease where the complications must not only be checked, but these complications can and must be avoided by a proper line of handling and proper line of treatment.

As to the feeding, one of the most important things in the treatment of typhoid fever is feeding, and more patients have been lost on account of the false idea that a certain limited amount of sweet milk is all a typhoid patient should have. There is no greater fallacy in the profession than the method of feeding typhoid fever patients in the past two or three decades, because some person started the idea thirty or fifty years ago that sweet milk was the diet for typhoid fever patients, and we have followed it blindly for a number of years, when in fact not a drop should be given. When you understand it is an infectious disease, with a rapid destruction of the albuminoids of the body; that it is a disease where granular degeneration and parenchymatous degeneration of the tissues of the body are taking place, produced by toxins, you must of necessity

feed patients better and more than you ever have done in the past.

The subject of typhoid feeding is an interesting one. It is a scientific one. You must give these patients sufficient food not only to carry on the ordinary functions of life, but also to take the place of the albuminoids that are burnt up so rapidly by the toxins of the disease. You must base your typhoid fever feeding on so many calories—at least two thousand calories. You must give the patient that much day after day if you would expect him to do as well as he ought to do. This is done not by feeding sweet milk. A patient with typhoid fever should never have a drop of sweet milk during the whole course of the disease. You can give him buttermilk and soups. I do not mean beef teas, but soups with vegetables cooked in them. You can give him starches and well-cooked starch, well cooked rice, well-cooked oatmeal. You can give him eggs and many substances other than milk. You must keep in mind constantly that an underfed typhoid fever patient is incomparably more liable to the more serious complications of perforation and of hemorrhage than is the overfed and properly fed typhoid fever patient, who is incomparably less liable to have these serious complications. These patients should be properly fed.

As to internal medication, it has been my practice for years to give every patient with typhoid fever a certain amount of medicinal treatment. There is not a practitioner who has not got a specific line of treatment for his typhoid fever cases. You can treat the fever as well as anybody can. You have a certain specific treatment which you use. I will say this: I give every case of typhoid fever 10 grains of urotropin ever 4 hours during the course of the fever, and have given it for 15 years. I give every patient five grains of salol every four to eight hours during the course of the disease. Why do I give it? These are not only intestinal antiseptics, but they are systemic antiseptics. If urotropin will stop suppuration of the mastoid cells and other pus conditions and cure such cases, why should it not get into the other tissues of the body? If urotropin will get into the meninges of the brain and it is the best remedy to give in certain types of meningeal trouble, such as acute poliomyelitis, and if urotropin can be given by the mouth and will relieve these conditions, why is it not the best of systemic drugs you can use? Again, you have from the tip of the tongue to the end of the anus a catarrhal condition of the alimentary canal, whether the patient has a diarrhea or constipation. If he has a catarrhal condition of the alimentary tract with or without ulceration, and particularly with ulceration in any other disease than typhoid fever, you would give large doses of bismuth, every eight hours, during the first forty to fifty hours, either the subnitrate of bismuth or the subgallate of bismuth. Every third

day they get a dose of castor oil. It is one of the best armaments you have in typhoid fever; it makes no difference whether the patient has diarrhea or not, he gets occasionally a dose of castor oil, and when he does not take castor oil he gets normal salt enema, whether he has diarrhea or not. You want to wash out the colon.

Liston H. Montgomery, Chicago, was asked to continue the discussion. He said: I wish to thank you, Mr. President, for this opportunity of inviting me to participate in the discussion of this symposium. I have very little to add, hence I will take only a moment or two of your time.

Dr. Boggess has practically covered what I would say upon this subject, especially with reference to the feeding of typhoid fever patients. Like he, I believe in a fairly liberal diet. I do not depend upon a so-called sweet milk diet. I give to some of my patients custards and boiled rice and soups, and sterilized water to all of them in fairly liberal quantities. At the onset of the disease, I give castor oil as a laxative, and I practically give no medication throughout the entire course of the disease, that is, to a moderately well developed case of typhoid fever, even if the temperature should rise to 105 F. Where there is delirium, we usually resort to cold applications to the head, forehead and occipital region. Frequent sponging is a good thing in connection with the treatment of typhoid fever. I believe in the frequent changing of the linen, and sponging the body with alcohol and water, equal parts, at a certain temperature seems to be very pleasant to the patient. I do not pretend to offer anything but what you are perfectly familiar with. As I have said, I believe in feeding these patients pretty liberally, and I do not mean by that, giving them raw meats or anything of that sort.

As sacred scripture says—or some one originated the expression, cleanliness is next to Godliness, I am a great advocate of that idea.

In Chicago, during the early part of the year, there were four prominent physicians seriously ill with typhoid fever, two of whom contracted the disease in a southern city, but not in "old Kentucky." I am glad to say. One of these gentlemen addressed you last night, Dr. Murphy, contracted the disease while on a visit to one of the southern cities. I am happy to report they have all recovered.

Recently I treated the case of a boy, twenty years of age, but I really think his convalescence was due more to the treatment and care that his mother gave him, than to any particular skill on my part. I watched the case carefully. It was a well developed case of typhoid. There was peritonitis, delirium, and a high fever of 105 and a traction, which gradually came down. This boy was given a liberal diet. If there were two or three movements daily of the bowels I gave nothing to control it, but allowed the typhoid infection to be eliminated from the system, or, as Dr. Boggess has said, to be disposed of in that

way. This young boy hardly received any medication. A good deal depended upon the careful nursing which he received from his mother. That of frequent changing of the linen, the sponging, and watching him carefully. He was ill about the usual time, viz: practically six weeks. He made a very auspicious convalescence with the least medication I have ever given any patient with typhoid fever.

Gentlemen, I realize this is your association, and your meeting, and the discussions I have heard during the past two days as your guest, will be one more of the pleasant reminiscences I have to cherish regarding genuine southern hospitality. This is not my first visit to the southland. Indeed, I have visited practically all the larger cities of every southern state, attending a meeting of some scientific association, perhaps, and I always leave with regret that I could not prolong my visits.

I thank you again for this mark of appreciation on your part, or that of your President in calling upon me to voice what little I had to say upon this important general disease, typhoid fever, and regret that I could not state something that would have been of greater interest.

A. D. Willmoth, Louisville: Since the President has allowed the discussion to drift far enough to include treatment, I want to take just a few moments time to speak of two complications that are of extreme importance to those of you who do general practice.

Those of you who read the Kentucky State Journal will remember that some few weeks ago I had an article in there on the complications of typhoid fever in which I dealt with the points I expected to call attention to this afternoon.

The first point I wish to call your attention to is the condition of perforation which you all fear so much, and one in which the surgeon is called in consultation so frequently. There are a few points in regard to perforation which I think the average practitioner has overlooked and likewise the surgeon—at least, up to the present time.

We are all familiar with the classical symptoms laid down in the textbooks. The stabbing pain in the side I will not detail, because you are as familiar with it as I am, but just bear in mind this: the pain in the side is not due to perforation, but to a localized peritonitis, and the perforation has taken place several hours before the patient has had pain. What is the result? If you call in a surgeon in the case now you have got a general distribution of the poison over a large surface of the abdominal cavity. What does that mean? It means that if you had been on the alert and did not care to assume the responsibility and wished to call a surgeon in consultation, you would have made the diagnosis in the preperforated stage. I mean every word of that, and I am not speaking from a standpoint of my own, because an excellent article appeared in the *Annals of Surgery* from a surgeon con-

neeted with the Presbyterian Hospital of New York City along this line. If you take a patient in bed, brentling with his mouth open, and commence at the right side and pass the hand over the abdomen in the following manner, you will get a marked localized rigidity. This examination should be carried out as follows.

The patient should be lying out horizontally, with both knees drawn up. The position should be a comfortable one. The mouth should be slightly open, and the patient is told to breathe quietly. The arms should be at the side and extended; the head should be kept directly in the middle line and in a comfortable angle of flexion. The room in which the patient is examined should be warm, for a cool room may cause slight tremors in the abdominal muscles, which will prevent a satisfactory examination. The bladder should be empty.

The examiner whose hands have been warmed if necessary, stands on one side of the patient and first very quietly and gently palpates with the flat of the hand those portions of the abdomen in which the patient does not complain of pain, tenderness, or discomfort, then gradually passes over to the effected parts. This gentle preliminary procedure affords to the examiner a rough idea of the general condition of the abdominal contents as to tumors, swellings, amount of adipose, points of tenderness, etc., and serves to allay a possible apprehension on the part of the patient. The next step is to determine the presence of rigidity in any of the abdominal muscles. This is best done with the most sensitive organs at our disposal—the finger-tips of the right hand. If the examiner is left-handed, those of the left hand should be used. The wrist and the finger-joints are all kept slightly flexed, and a succession of short, but very delicate "pushes" is made with them over the muscle that is being tested. It requires numbers of examinations as a rule, for the beginner to acquire the ability to detect slight differences in the amount of rigidity present in different muscles or in the various positions of the same muscle; but the acquisition of this power is well worth infinite pains and patience on his part. The two sets of muscles which should be tested with special care for rigidity in typical patients are the recti and lateral abdominal muscles.

Owing to the usual preponderance of the dangerous ulcers in those coils of small intestines, that are commonly found in the right iliac fossa and right paraumbilical region, the right rectus and right lateral muscles should receive first attention. Taking into account the normal difference in muscle tone between the three segments of the rectus muscle, a preponderance of rigidity in any one of the three sections of the right rectus over that found in the corresponding section of the left is first to be noted. Then a rigidity of the right lateral muscle is sought for as compared with the same layer on the left side.

The amount of abdominal tenderness will depend on the condition existing in the abdomen, in those cases where the folds of gut are kept separated by a fluid exudate the tenderness will be slow in appearing and will of necessity be of mild form at least for several hours.

In the examination to elicit tenderness, extreme care should be used lest we should rupture a weakened bowel wall, remove protective lymph and disseminate infection over an area that nature has or will protect.

This localized rigidity and tenderness should be a sign board pointing you in the right direction. Sooner or later something will happen which nature is protecting in this board line way. Look out for that. Call a surgeon in consultation early because there is a better chance to operate and better results are achieved. The operation can be done under local anaesthesia by the hydrochlorate of quinine and urea.

The operation does not necessitate a general anesthetic and only requires a few minutes, usually about 10 to 15 minutes being all the time required.

A second complication you are all familiar with is that connected with the gall-bladder. Here, again, do we see typhoid infection spending its force in a virulent manner.

I am glad to see that one of the internists who preceded me referred to the administration of urotropin, because we know if there is any drug at all that does in a way sterilize the contents of the bladder it is urotropin, and it certainly acts as a most excellent preventive in guarding against infection in the gall-bladder, which later on might lead to acute cholecystitis or acute empyema of the gall-bladder. In these conditions where infection takes place and acute infection of the gall-bladder occurs, where there is tenderness in the region of the gall-bladder, with stiffness of the muscles, it is a surgical case. I take it, we do not want to take such a case alone, we do not want to shoulder the entire responsibility of the case because it is serious, but if you do not do surgery yourself, you should call in some one who does surgery as promptly as possible, because, sooner, or later, in all probability, there will be perforation of the gall-bladder. These cases are not inoperable, and to-day, any surgeon who refuses to operate for you when he sees the case early, even though there be a perforation of the gall-bladder, is a surgical coward, and no patient should be denied the chance of getting well from a prompt surgical operation where his gall-bladder is perforated. I have operated on many patients who seem to be in *extremis* from perforation of the gall-bladder and other complications, and you will be surprised to see how quickly these patients will rally with local anesthesia, or with a little general anesthesia you can rapidly go down on the gall-bladder and open it up, and drain it. You will

be surprised to see how quickly these patients, whom you consider dead, will rally.

J. S. Lock, Barbourville: I do not wish to say anything in particular regarding the treatment of these cases, for I heartily endorse everything that has been said; but I want to say in connection with the paper of Mr. Hansen, let us get at the beginning and prevent these troubles and we won't have the trouble of treating them after they develop. Let us try to prevent the spread of typhoid fever. You know it is said that you cannot teach an old dog new tricks. Let us go out in the country and in the rural districts where the children are not being taught by their parents the importance of cleanliness, are not being taught to take care of the discharges from these cases, and begin to bring them up. Let us as country doctors go to the country schools and talk to the children and educate them along the lines of sanitation. You will pardon me for referring to myself, but I have been all over my county this year and in most of the adjoining counties trying to teach them sanitation, and you will be surprised to know the number of children that will not take a drink of water unless they know where it comes from and they think that water is all right. You will be surprised to go back into the hills and see the number of children that carry individual drinking cups. They want to know about these things. You will be surprised to hear the little fellows instructing one another what they should do to take care of themselves, and they go home and the parents have come to me and told me in my office what the children have said. They say that the children have told them things they had never thought of. I think that is the primary step. Let us remember that and try and get these matters before the people before they contract typhoid fever. If we can prevent typhoid fever, why should we have it? Let us think along this line, and then if we get it, we can treat it, but let us not get it.

W. W. Anderson, Newport: One little thing we frequently overlook as a source of infection in the home and the spreading of that infection from one individual to another is—and I have noticed it quite frequently—the unfortunate habit of the mother of kissing her sick child. It is so obvious that this should not be done that we forget to mention it to the mother, and it is so natural for her to do it in the outburst of her affection for a sick child that it becomes a source of infection. Again, the little patient may refuse to take a glass of buttermilk. He may take a sip or two, and in order to show that it is good the mother will taste some of it herself, and I have seen infection spread in that way.

In regard to the treatment, one of the speakers referred to the use of phenacetin as an antipyretic. Undoubtedly, it will make the patient temporarily more comfortable, but I would file an objection to the use of remedies of that kind un-

less there be some clear indication that cannot be met in a simpler and better way. How often do we find in cases of typhoid, especially if the use of these remedies be prolonged, that the patient develops myocardial insufficiency, edema of the extremities, shortness of breath and a relaxed muscular tone lasting for a long time. Let us keep away from the coal tar products unless there is a clear indication for their use which cannot be met by something else which is safer, as, for instance, the cold baths.

One of the speakers referred to the difficulty of giving a cold bath because patients have not a bath tub. You do not need a bath tub. Sponging will be better in my judgment than a cold bath. You do not agitate the patient as you would by carrying him from room to room. I do not use a tub at all, although my patients sometimes have them.

Another drug that has been used, but I do not know whether it was mentioned or not, and that is alcohol. I believe that alcohol is always a narcotic, always a depressant in its effect and always harmful in typhoid fever cases.

I was very glad to hear Dr. Willmoth's suggestion with reference to perforation, and in connection with it he mentioned hemorrhage. If we will keep the abdomen free from distension by the use of castor oil, or by the use of intestinal antiseptics, and a favorite with me is boric acid, and use turpentine internally, externally and eternally, if necessary, the patient will be free from tympanites, and he is not so liable to have a serious hemorrhage or a perforation.

One of the essayists, if I understood him correctly, said that if you have hyperpyrexia you may get meningitis. If the patient has a hyperpyrexia he probably has meningitis. At least, you will find hyperpyrexia with the meningitis. Perhaps this is what he intended to say.

It has been my fortune to have treated 150 cases of typhoid fever ranging in age from five months to sixty years, with six deaths thus far. My treatment principally has been boric acid, ten grain doses every three hours in some digestive elixir, something to make it as palatable as possible, and for the sake of influencing the patient's mind and satisfying the taste, I use elixir pepsin at one time, and some other form of elixir the next time. It does the patient's mind good to see a change in the color of the bottle and to have a difference in taste to the tongue. That helps a little bit.

I am glad to have heard this whole subject gone over again because there is always something good in it.

Arthur T. McCormack, Bowling Green: I did not realize how old a physician I was until I listened to this learned discussion on typhoid fever. I am almost afraid to confess that I am using drugs in the treatment of typhoid fever. I would not make this confession if I had not been taught to use drugs in the treatment of this

disease by the late Dr. William Bailey, who administered them to me with beneficial results when I had it. I would like to say in passing that Dr. Bailey was one of the most beautiful characters I have known in medicine. I had typhoid fever myself, and was in my third relapse, and in the anxiety of my professional attendant Dr. Bailey was called in consultation. I was running a temperature between 103 and 105. I was very sick. Dr. Bailey wrote a prescription for me which I have used since that time and have given comfort to poor sufferers by its administration. This prescription consists of forty-eight grains of euquinine; forty-eight grains of phenacetin, and forty-eight grains of sodium sulphocarbolate. He made forty-eight capsules. I took one of them every two hours until I took them all within forty-eight hours. At the end of the forty-eight hours my temperature, which had been high, attended with delirium and uncomfortable nervous symptoms for five days, was reduced to 101, and it never went above that during the following three days of that illness. I continued to get along nicely and got well, as you see. I have had that experience in a number of cases of typhoid fever that I have seen early. They were true cases of typhoid fever. They were not cases of typhoid malarial fever, I do not believe there are such cases except in rare instances. I do not know whether there is a sufficiently strong inhibitory action in the quinin which acts on the development of the toxins or what it is, but in my hands that prescription has been satisfactory when given in the early stages of typhoid in fairly strong adults who were not liable to great depression. Following that first administration I have been in the habit of giving two grains of phenacetin, where the temperature was above 102 1-2. I have seen comparatively few typhoid cases that have required much other medication than that and the laxative, castor oil.

I was very much interested in reading an article by Dr. Cole, of the Rockefeller Institute, New York, on typhoid fever; but I do not believe that doctors have become useless in treating typhoid fever cases. I believe you and I are treating cases of typhoid fever every day and are relieving them. When we do not treat them the average death rate will be quite high. Fully ten per cent. of them will die, and I do not believe that ten per cent. of them should die. This is too great a mortality.

E. Bransom, Henderson: I am one of those physicians who believes that pretty nearly anything will cure typhoid fever, and I do not give very much medicine. In the last year or so I have been giving the yellow iodid of mercury in one hundredth grain doses, given three times a day, and have had good success with it. I have not lost more than one per cent. of the cases.

About fifteen years ago, when I was visiting the Polyclinic in Chicago, Dr. Smith was experi-

menting with baths, and while I was there he told me that he had treated one hundred cases of typhoid fever with baths, and ninety-eight out of the hundred recovered. One patient died within six hours after he was brought to the hospital; the other one died in twelve hours. He used absolutely nothing but water. He puts these patients in a large tub and turns the water on them, and the temperature would soon drop down to 101. He gave them no medicine. He said he had achieved just as good results without the use of medicine. As I have said, I have used very little medicine in the last year or so. I have used the yellow iodid of mercury in one-hundredth grain doses and have gotten splendid results. If these patients should have too much diarrhea, I correct it. The same thing holds true with regard to hemorrhage, and I correct it. But the ordinary cases of typhoid fever I allow to go on and resort to sponging for the excessive fever, and either this is done by the parents or by the nurse.

With reference to giving milk, I give sweet milk. I do not see any difference and believe they do as well on sweet milk as with other kinds of milk. I get good results with sweet milk.

S. L. Henry, Morganfield: When I began the practice of medicine more than thirty years ago, typhoid fever was quite prevalent in my section of the country. We had cases almost the year round. I kept a record of cases until I had treated more than four hundred, with only seven deaths. I think the cause of so much typhoid fever at that time, was due to the fact that the water supply was mostly from springs, and shallow wells. However, since our people have quit the use of spring water, and have resorted to deep wells, we have but very little typhoid fever. I think the most important part of typhoid fever, is the treatment, and the most important part of the treatment is rest. My plan is to let the patient rest as much as possible. I don't like to have my patient worried every little while about their temperature and pulse. I never put them in the cold bath, or use the cold pack. At the onset, I usually give a light purgative, I prefer calomel as it is both antiseptic and diuretic. I endorse the antiseptic treatment. Bismuth, salol, creasote, turpentine and the sulphocarbulates are all good, if used at the proper time. I have my patients sponged occasionally with tepid water to keep them in a sanitary condition. I also have them sponged with dilute alcohol, to make the skin firm, and keep it from breaking down. As typhoid fever is a self-limited disease, if we can keep the patient well nourished and give them plenty of rest, they will need but little medicine. As long as the temperature is below 103, I seldom give any medicine to reduce it. By trying to reduce the fever, we often weaken the patient. I have often seen patients that I thought were nursed to death. One kind of medicine given every two hours, another every two or three hours, and perhaps another every

three hours, with bathing and sponging between times, temperature and pulse to be taken every two or three hours with nourishment between times. When you come to figure it up, the patient gets perhaps thirty or forty minutes at a time for rest. Well these cases will all died, they are worried to death. We can take any man in this house put him on a low diet, and only allow half an hour or even an hour at a time for rest, and I don't believe he would live four weeks. I know I would not. As to nourishment I am partial to milk. If the bowels are inclined to be constipated I give buttermilk, if loose I give sweet milk. Sometimes I use lime water with it, and sometimes pepsin and I have good results.

V. A. Stille, Benton, (Closing the discussion on his part): I have very little further to say except to thank the gentlemen for their free discussion of my paper. I left out a good many things that were brought out in the discussion. Every case is a law unto itself. You may want to give one remedy at one time, and another remedy at another time.

In regard to the use of phenacetin as an antipyretic, of course, you want to give as small a dose of medicine as you can under these circumstances. You may give salol at one time, and bismuth or sulphocarbolate of sodium. But the case must be individualized and treated accordingly.

So far as typhnites is concerned, there is nothing to be compared with turpentine either internally or externally for the relief of it.

With reference to the diet, it should be liberal. There is no doubt about this. I am not particularly in favor of any form of milk, but if I should, I prefer buttermilk. I use soups of all kinds.

The last speaker spoke of the importance of not worrying these patients by giving them too much medication. We should give them medicines that are as nearly compatible as possible, let the patient rest, and keep the other members of the family from having typhoid fever.

Paul Hansen, Bowling Green, (Closing the discussion): The trend of the discussion on these papers has been somewhat outside of my province as a sanitary engineer, in that it has dealt with the cure of typhoid fever cases rather than with the prevention of typhoid infection. However, it has been extremely interesting to me, and I have learned in a general way how complex and absorbing this great subject is, and it suggests an explanation to my mind of the rather frequent neglect on the part of the medical profession with reference to preventive measures.

Sanitarians and sanitary engineers have had occasion to feel some disappointment over the manner in which projects for water purification and sewerage installation have been received by physicians. They have not only failed to make intelligent inquiry into the character of these projects, but generally neglected to back up such projects with the force of their approval.

It is a well known fact that the people in general will listen to the advice of their physicians far more quickly than they will listen to the advice of sanitarians or sanitary engineers, and after all it is only through the assistance of practicing physicians that sanitarians and sanitary engineers can carry out the work in which they are specialists. It is only rarely that a sanitary engineer has the opportunity to place his views clearly before the people directly, so that it is nearly always necessary for him to count upon the helpful mediation of physicians.

There are some instances in which physicians, though well meaning and demanding sanitary improvement where such improvement is necessary, have nevertheless blocked direct progress by assuming too great a knowledge of subjects in which they are not specialists. A striking instance of this occurred in Washington, D. C., where a Commission of expert sanitary engineers recommended a form of filtration for the water supply which is now successfully in use in Louisville, Cincinnati and many other large American cities, as most economical and at the same time thoroughly efficient. It developed, however, that this method involved the use of alum as a coagulant, and immediately a storm of protest went up from the physicians of the city against the use of this chemical, on the grounds that it was detrimental to health. Had they made proper inquiry they would have been apprised of the fact that the alum is used in such a way that absolutely none of it can enter the filtered water and moreover the quantities used are so minute that even supposing the whole of it went into the filtered water there would be no injurious results to the health of the community. Nevertheless, the protest of the physicians was so strong and carried such weight with the public that the engineers were obliged to accede to their demands and put in another form of filtration, which was recognized by the engineers as not being adaptable to Potomac River water. Not only that, but the filtration plant finally adopted cost the Government more than \$1,000,000 more for original construction than would the plant recommended by the engineers. As might have been anticipated, the filtration plant finally installed failed to give entirely satisfactory results and it became ultimately necessary to precede filtration by treatment with alum after all. The physicians perceiving their error after the damage had been done, were manly enough, however, to rescind their former action and place themselves on record as having no objection to the use of alum when properly applied.

The work of the sanitarian is quite as distinct and complex a profession as the practice of medicine and the same is true of the profession of sanitary engineering. The physicians should try to understand the work that men in these professions are doing, without necessarily going into the technical details or other minutiae of the

work, and they should stand ready to support the efforts of sanitarians and sanitary engineers, for without such support but little progress can be made along the lines of improving the public health conditions.

DIFFERENTIAL DIAGNOSIS BETWEEN GLAUCOMA, IRITIS AND CONJUNCTIVITIS.*

By H. G. REYNOLDS, Paducah.

In assigning subjects our secretary has unfortunately for me, and I might add also for you, given me one which is not only old but one to which very little of recent knowledge has been added. This fact, however, does not detract from the importance of the subject.

It would seem that the symptoms of these three diseases and their characteristic differential points would be sufficient to make a definite diagnosis in any one of them, and in the majority of the cases it is, but too frequently we have, especially in glaucoma, overlooked and in many cases wrongly diagnosed by the general physician as neuralgia, stomach trouble, etc., and treatment too long delayed to do for the patient that thing which will prevent almost certain blindness.

In differentiating between iritis and glaucoma we will first consider the symptoms that are more or less common to both diseases in a typical case.

Pain is usually common to both and, is in these as well as in all diseases when present, one of the most important symptoms.

In iritis the pain is more intense at night whereas in glaucoma it is not necessarily nocturnal but may be so intense as to cause nausea and vomiting.

Increased tension a constant symptom of glaucoma and causing all of the other symptoms may be an accompaniment of iritis or may be produced by iritic adhesions.

A patient of this type makes for the doctor a case which is a trial and tribulation as to treatment.

As an iritis with increased tension and intense pain may present to the internist a case difficult of diagnosis, and, in two diseases where a mistake in using atropin in the one may prove destructive and, a failure to use it in the other cause a loss of very valuable time and cripple an eye the importance of absolutely differentiating between them is apparent.

Fortunately the shape and size of the pupil, and depth of the anterior chamber are to be relied on and, deposits on the posterior surface of the cornea or the age and history of the case, the integrity of the field of vision

are usually sufficient symptoms to make a diagnosis.

The deposit on the cornea while not constant yet when seen with other characteristic symptoms indicate iritis.

I might mention here that it is often difficult to determine where an iritis merges into a cystitis or differentiate between the two, and although our subject deals only with iritis it is impossible to entirely separate them.

The chief symptoms, as I have mentioned, in all forms of iritis is pain especially at night, along with this we have intolerance of light, impairment of sight, pericorneal injection, iris discoloration, turbidity of the aqueous, irregularity of the pupil, general malaise and often a characteristic odor of the breath. While these are symptoms typical of a case of acute iritis we may have a form where Atropin instead of giving the customary relief from pain causes instead increased tension, intensification of the pain, edema of the upper lid, somewhat clouding the diagnosis.

A symptom I would like to emphasize and, which is characteristic in acute iritis, is the odor of the breath. The attention of the doctor is often called to the iris by this symptom of the trouble even before a thorough examination of the eye is made.

The depth of the anterior chamber, anaesthesia of the cornea, dilated pupil and above all increase in tension, accompanied with intense constant pain, with halo around the light presents to us a typical case of glaucoma.

The ordinary method of taking the tension of making pressure with fore finger of both hands is practical and in experienced hands is effective. With the tonometer I have had no experience.

Cupping of the optic disc while a valuable symptom in diagnosing glaucoma is not always available because of the obscuration of the fundus. A pathological cupping of the nerve and arterial pulsation either may exist with less serious effects, but this combination is pathognomonic of glaucoma.

The differentiating of conjunctivitis from the other two diseases can be made by considering the presence of superficial and deep congestion of the conjunctiva, depth of the anterior chamber, color of the iris, reaction of the pupil to light, convergence, and accommodation, also the condition of the media, fundus and tension.

In referring to iritis I have purposely referred to the disease in a general way because although the symptoms vary somewhat according to the character and intensity of the inflammation but on the whole are rather constant.

*Read before the Kentucky State Medical Association, Paducah.

I have referred to acute and sub-acute glaucoma because I do not think it possible to confound any other form of the disease with iritis or conjunctivitis.

DISCUSSION.

Adolph O. Pfingst, Louisville: It seems to me in considering the differential diagnosis of these diseases of the eye there is one point that ought to be emphasized before a body of general practitioners, and that is, to observe more closely the condition of the pupils. That is the first thing we notice, particularly those of us who have seen a good deal of the eye. We see at once whether there is good reaction to light, whether the pupils are round or irregular, etc. The specialist sees all of this almost instinctively. If we watch more carefully the condition of the pupils, there is no reason why a case of conjunctivitis should be confounded with iritis or glaucoma. In a case of conjunctivitis you have a clear anterior chamber, and clear cornea, and as soon as light is thrown into the eye you have rapidly reacting pupils, unless bound down by old adhesions. I do not see how one could mistake this for one of the other two conditions.

As to iritis and glaucoma, we should hardly confound these two affections where we have pronounced symptoms, such as wide pupil, increased tension, etc. However, we do have trouble sometimes in differentiating an acute glaucoma from an iritis where symptoms are not pronounced. The wide rigid pupil, hazy cornea, increased tension and possibly the nasal limitation of the field of vision, and the nature of the pericorneal redness would be distinguishing features of glaucoma, and the discolored iris, constricted pupil and tendency to posterior synechia, and the absence of the glaucomatous symptoms would be indicative of iritis. The pain of iritis, which is nearly always worse at night, is usually not as severe as in the acute attacks of glaucoma.

I cannot refrain from saying a few words about the optometrists. While we recognize the need of opticians who stand in the same relation with the oculist as the pharmacist does to the practitioner, we must not confuse these with the traveling optician who is endeavoring to invade the domain of medicine. The optometrist without any preliminary education in medicine are demanding the same privilege of treating diseases of the eye as a specialist who has devoted four years to the study of general medicine before equipping himself for his specialty. Where is the justice of this? And it is the very thing that the optometrists are trying to accomplish by an act of our legislature. Every practitioner should understand the situation and help defeat such a measure. I believe too that more practitioners should equip themselves for taking care of simple refraction and thereby do away with

the necessity of their people consulting men not equipped for the work they claim to do.

I have always argued that opticians do not so much harm our people by what they do to them, but assuring the patient that glasses will relieve them, they lose for the patient valuable time before he realizes that he should have consulted someone who could judge of the condition of the eyes.

Take a case of chronic glaucoma, with nothing but a sluggish pupil to denote a diseased eye. The inexperienced simply see if they can fit a pair of glasses, and are satisfied if they get two-thirds vision without knowing the cause of it. When a patient has less than normal vision, we ought to find the cause of it. If the vision can not be brought to normal, we can by seeing inside the eye, look for pathological condition and determine the cause of it.

These remarks are a little foreign to the paper, but I could not help saying a word on this subject at this time, and I hope that Dr. Hall will be allowed to speak of this subject.

D. M. Griffith, Owensboro: I do not believe you can teach anybody to differentiate between glaucoma and iritis and eliminate conjunctivitis by any rule of reason. You must have, as Dr. Pfingst has told us, that large knowledge which can only come from experience. The inspection of the iritis is of particular importance in differentiating these diseases; but there are some things we see intuitively. When we see a case, if we have had a large experience, we can generally intelligently classify it and tell whether it is glaucoma or iritis. Glaucoma, iritis, and conjunctivitis, as Dr. Reynolds has told us, are quite common; but there is something that is characteristic of each affection. For instance, iritis is attended with a boring, bearing down pain; while glaucoma is attended with a fierce, tense and lancinating sort of pain. On the other hand, conjunctivitis is accompanied with a rather burning sort of pain.

I believe the general practitioner ought to be exceedingly cautious about ever prescribing anything which would tend in the slightest or least possible manner to increase tension because he incurs the risk or danger of precipitating a case of glaucoma in a condition that he cannot detect. Sometimes even specialists are mistaken. We specialists have seen some sad sights following the use of drugs used in the eye. I recall one case in which I removed both eyes from a lady, sixty years of age. She was a charming, fascinating woman. One of the best general practitioners in the State of Kentucky had prescribed atropin and produced glaucoma. After his death another physician saw this woman and said she had glaucoma in the other eye. I enucleated both eyes. This one experience ought to be sufficient to warn any man, who has not had great experience, in prescribing a mydriatic or cycloplegic under any condition. As Dr.

Pfingst has said, it is little or no trouble to the man of experience, whether he be a specialist or general practitioner, to make a differential diagnosis between these diseases of the eye, but unless he has had that experience, he is like a man fooling with dynamite and may destroy the sight of the patient, and the most important thing we can say to the general practitioner is that, if there is one iota of doubt, he should call in some man who has had that experience.

Gaylord C. Hall, Louisville: I have enjoyed Dr. Reynold's paper very much. He has handled a trite subject in a masterly manner. There is very little to add to what he has said except that I would like to qualify his statements in one respect, and that is the great difficulty we have in differentiating these diseases in **mild cases**. It is easy enough if we have a fulminating case of conjunctivitis, with a profuse purulent discharge, to recognize it. If we have an acute attack of glaucoma, with entire absence of vision, with widely dilated pupil, and a very hard eyeball, and absence of the anterior chamber, it is easy to diagnose that condition. If we have, on the other hand, an acute attack of iritis, with a pin-point pupil, with discoloration of the iris, with an acute pain which comes on and is worst at night, it is easy to diagnose that. It is in the mild cases that difficulty in diagnosis presents itself. Where there is some photophobia, as there is in all cases, where the eye is sensitive, and the redness is not so intense, it is difficult to differentiate between conjunctivitis and ciliary injection.

In addition to the three diseases the doctor took up, some of the mild cases of the obscure forms of keratitis are quite difficult to differentiate from iritis, because in both of them you have symptoms which are most prominent. First, photophobia; second, a discharge, not of purulent material or of mucus, but of tears, and you also have in such cases a contracted pupil. Unless you get illumination and carefully examine the pupil, you may fall down on the differential diagnosis, not that it makes a great difference in that particular instance, but sometimes it is difficult to put your finger on whether it is a beginning keratitis or an iritis. In such a case atropin would be indicated immediately. There is where we have no doubt of the differentiation between glaucoma and iritis. The attention of the general practitioner should be called to the fact that one of the most prominent symptoms of glaucoma is increased intraocular tension; consequently, the first thing a man would think of in making an examination would be to palpate the eyeball through the upper lid, and it is well known to those of us who handle many of these cases that there is a tender spot in cases of iritis at this point, and that if you palpate or attempt to do so through the upper lid to see whether the eyeball has increased tension or not, the patient will flinch nearly every time.

This spot of tenderness was described at first by a French writer. It is quite characteristic. In taking the tension in cases of iritis, you will find intense pain when you palpate, which is due to congestion of the ciliary body which must not be mistaken for the hardened eyeball of glaucoma.

James H. Lackey, Canton: I am a general practitioner. Some one has remarked that the general practitioner needed more information that he usually has on the subject of the eye, and I am very much obliged to the gentlemen for their discussion. During an experience extending over forty years I have met with all kinds of sore eyes or eye diseases. I remember once a young man came to me with the eye closed very hard, and it took both of my fingers and all the strength I had to open the eye. After a few days' treatment he decided that I could not do anything for him, and he thought he would go to Hot Springs, Arkansas. He decided to go there, but I advised him to go to Louisville to a friend of mine. He started, was gone four or five days, and returned rather more hurriedly than I had expected. I said to him, "Well, John, how did you come out with your eye?" He replied, "It is all right. I started for Louisville and when I got to Clarksville I never thought anything more about my eye. When I got to Louisville I thought about the address you gave me, and come to find out my eye was wide open because I had never been out of the county and found use for it and began to use it." (Laughter).

That is a little bit of experience. I did not get up to talk on the subject of the eye.

Dr. Pfingst, of Louisville, spoke of a subject that I know a little something about. I had the honor of being appointed chairman of the Committee on Public Health and am familiar with the work done in the last session of the legislature. Most of you know that these optometrists have been trying to pass a certain bill, and they have been the most persistent, anxious, eager men I have had to contend with. I take the position that Dr. Pfingst does, namely, that they know nothing about fitting glasses properly, and every person that needs glasses should be placed in the hands of an eye specialist. Of course, that is not possible always, and the objection I have to the optometrists is the fact that they are making another trust for us. I am against the trust always, and hence, when we came to report the bill back I said I would like to make a talk on the subject, and by way of information for the legislature I had occasion to say all I could possibly against the bill. I had the honor or dishonor of trying to defeat the bill. We relegated it to oblivion so far as we are concerned. I hope you gentlemen will use your influence to have the bill defeated when it comes up in the next legislature.

Arthur T. McCormack, Bowling Green: Dr.

Pfingst has opened up a subject that should properly come before the House of Delegates but it is one of such extreme importance that I think it might be well to discuss it more fully here because it is a matter entirely of education of laymen. It is a matter about which the profession is already informed, but there is a real danger to every man with diseased eyes in the State of Kentucky right now, or who will be in the State of Kentucky in the future.

In a number of states a mistake has been made of permitting the optometrists, that is, the jewelers and others to fit and sell glasses by simply testing vision, trying glasses on, until they find a pair that makes the man see better than he did without them, and licensing them to treat diseases of the eye. Now, we have to be specialists, and I fully agree with the gentlemen in that respect, to differentiate between certain diseases of the eye. I always like to hear papers of the character read by Dr. Reynolds, because the simplicity with which he, Dr. Pfingst, Dr. Griffith, or Dr. Hall can make a diagnosis in these conditions, the ease with which they can do it from their description but emphasizes our incompetency to do it. I listen to such men with reverence because, while I was prepared as you all were in an elementary way to take up and treat these conditions, I know I cannot do it. I know I have had more training than all the optometrists in Kentucky put together in making differential diagnosis of diseases of the eye, and if I am unable to do that, then I am quite confident they are. If we can say that to our legislators, they will be just as anxious as we are to have the right thing done. They want to do the best they can; they want to do what is best for the people of the State. Many of our legislators go to Frankfort without knowing a thing about this. There is not a doctor in the State that does not know about it, but very few of our physicians think of the optometrists, and when our legislature is in session at Frankfort there will be these persistent, smooth, commercial lot of men who are making money out of it, who are selling glasses for profit, who go to the members of the legislature and appeal to them with every argument against physicians and present every argument in favor of the passage of such a bill as they want to put through. We cannot always have such men as Dr. Lackey present. I am sure, if the legislature was composed entirely of doctors he would be elected a representative for life. But some member of the legislature has to defend the people of the State. If half of the members here when they go home will see the man that is going to be elected to the next session of the legislature, no matter whether he be a Democrat or Republican, and talk to him for five minutes about such pernicious legislation, he can give that legislator more instruction in five minutes than he could learn in a year after he gets to Frankfort. He has confidence in you, hence

do not deceive him about the matter. He knows you have no more commercial interest in the thing than he has, and if you will instruct him on that point you can do much good for your people in this very important matter.

Dr. Hall has investigated the fight that has been made in every state. There is an article by him in the current issue of our JOURNAL. If it is the wish of the members he will continue to write additional articles on the subject, so that the profession and laymen of the State can be instructed in regard to this matter.

The Federation of Women's Clubs has appointed a strong committee to take action in this matter. They understand the importance of it. They have been in the mountains and have seen people made blind by improper treatment. They have seen cases of trachoma treated by putting tin spectacles on people and calling them gold. They have seen case after case of blindness in which the traveling opticians have sold perfectly plain glasses and have put rose water into the eyes, and they ask that this condition be legalized. It is an insult to the intelligence of any body of men that they should ask their approval of such a bill. Members of the legislature do not know anything about this matter beforehand, but when they go to Frankfort they should be properly instructed, because there is no more important health proposition before the people of the State to-day than this.

W. W. Richmond, Clinton: I know but very little about the diseases of the eye, notwithstanding, as Dr. McCormack has said of himself, in my early training I had the preliminary qualifications about as good as most practitioners to begin with.

Forty years ago specialists, in Kentucky, were not so numerous as they are now. There were one or two in Louisville and perhaps the same number in Lexington and none in any other part of the State.

There was an ignorant class of men who traveled through the country claiming to be specialists, who pretended to treat the eyes, and who sold spectacles; a class of men similar to those are clamoring for legislation to permit them to do the same thing now.

The general practitioners treated diseases of the eye, and considering his opportunity, succeeded fairly well. I remember quite distinctly when my preceptor, the late Dr. Geo. Beeler, of Clinton, Ky., who was a general practitioner of medicine, treated diseases of the eye, and also did some successful operations upon the eye, notably iridectomy and operations for cataract, entropion, ectopion, etc.

I remember upon one occasion he operated upon a lady eighty years old for cataract, and after the operation she was enabled to read the finest print of a newspaper. I assisted Dr. Beeler in many of these operations. In some of them the operations were done in log cabins

poorly lighted; on one occasion we climbed upon the roof of the house and took a part of the roof off in order to get sufficient light in which to do the operation. It was a rare opportunity for me, as Dr. Beeler's assistant, which enabled me to treat many diseases of the eye successfully.

I want to compliment Dr. Reynolds' paper; it is both scientific and practical—a paper that the general practitioner can appreciate as well as the specialist.

In conclusion allow me to say that I heartily accord with Dr. McCormack in his suggestion in reference to legislation. When we go home we should have a talk with our prospective representatives; we should explain to them the importance of the legislation we need, show them that all the legislation that the doctors want is directly in the interest of the people, bring to bear, the influence of all the doctors in the district, upon the representative, and the chances are he will get right and stay right. If there was a representative in every district in the State such as we have in the First—my district—we could have any bill passed in the legislature we would want. I refer to the Hon. W. J. Jackson, of Hickman county. He is the representative of the First District in the State for the third time. He was elected each time, largely through the influence of the doctors. He is the doctors' friend. By the combined influence of the doctors they could elect the representative from every district in the State. Let's try it.

James S. Lock, Barhousville: The condition in the mountains has been referred to. We have two men in our section of the country who make it a business of going through our country once a month or every two or three months, especially on court days, and reap a harvest. They are deadbeats, and they are ruining the eyes of the people. We have no way to get at them. We cannot do anything. My patients come to me and talk about the condition of their eyes and ask me questions about these men. They have been to their houses and have probably told them that they have some trouble with their eyes. They will go to the houses of these people and sit there for hours and plead with them to buy glasses. We ought to have some way by which we could get at these people and stop them from doing this. I am a member of the council in my own town and I shall try to do what I can. I had a license of five dollars a day placed on these men, but they rebelled against it. We ought to have some way to put these men out of business. I would like to see some sort of legislation enacted that would prevent them from doing this. I want to say, we from our district think we will send a doctor to the Senate. If we do, you can count on him. As to our representative, I have been at work with him, and by the time he gets to the legislature we can count on him. I regret very much to say that there are some doctors who will stoop so low as

to take these men in with them for the purpose of getting a commission on the sales they make or for rent of the office while they are with them. They will take them in and aid them in this imposition. I think we ought to wake up, and if a doctor does that kind of thing, we ought to see to it that he does not do it. We ought to go to him and talk to him as a brother and show that he has more commercialism in his makeup than good sense for practice. We should tell him that he is doing wrong. Let us educate the people. If we cannot do it by legislation, we ought to educate them to let these men alone and show them that it is a disadvantage to them, and not lead them to believe we are advising against this for some gain we may get ourselves.

M. M. Moss, Franklin: From a legislative standpoint, our representative and senator are both my personal friends. I have talked to these men along the lines that have been indicated, and I can say that both of them are men of sound mind and good heart, and they are heartily in favor of any legislation for the protection of the people of Kentucky from these troubles. In talking with our representatives and instructing them what to do in regard to such a matter as this it is very hard to disabuse the mind of the average legislator that we are not legislating in the interest of the doctor instead of the people. If we can get that idea out of their heads and get into their minds that this legislation which we propose is for the interest of the people of Kentucky and against the interest of the doctor, I believe we could get such legislation through as we may desire without much trouble. So far as our representative and senator are concerned, they are right on all propositions.

Gaylord C. Hall, Louisville: There are certain things which ought to be emphasized. I am delighted personally to find out that the profession of Kentucky is so widely awake to this thing. From the large amount of correspondence I have had there were some men who fought this thing very bitterly. In Pennsylvania they defeated such legislation, and in Massachusetts they were likewise successful. In New York they have been unsuccessful. One reason why this law was passed was on account of the apathy of the general profession. You could not make them see that they had anything to do with such a bill. The result of it was there were three or four who did the work. They went to the state senate and pleaded their cause. They had three hundred opticians who simply turned everything they could upside down to have the bill passed. The bill passed because there were three hundred against three. That is the whole proposition. If we want a bill passed to protect the people of the state, we must put forth every effort to have it done. Let us see what they did in New York. They got the endorsement of seven hundred regular general physicians for this bill. They went

to the physicians and said to them, You have a lot of traveling vendors of spectacles going around throughout the state and injuring people's eyes and selling glasses irrespective of whether they need glasses or not. If you give us your endorsement, we will have a Board of Optometry appointed, and this board will pass upon the qualifications of the men and we will run the fellows who cannot pass the examination out of business. But they did not do it. A Board of Optometry was appointed, but these men have very few restrictions.

Optometry bills have been introduced and passed the legislatures of twenty-four states in the Union, and it has been the unanimous opinion that latterly the board has become lax and they would license anybody that wanted a license irrespective of the qualifications and training. Of course, you understand, if this bill passes, you cannot restrict those fellows who are already in practice. They will get the right without any examination. The proposition is simple: we have got to keep awake on this thing and must not be led into signing or endorsing a bill by false promises of this kind, working for it with the idea they are going to run out of business the traveling opticians. These men do not want the right to sell spectacles. They do that now. What they want is the right to treat diseases of the eye without ever having passed a medical examination or without having any of the qualifications to prove that they are competent to treat diseases of the eye. The optometry boards of most states ask medical questions about the anatomy of the eye, the nerve supply of the eye, what is conjunctivitis, what is glaucoma, and how to differentiate these conditions from cataract. What is the difference between glaucoma and iritis. All these things are purely medical questions, and should have no possible relationship to the fitting of glasses. So you see this is a covert attempt to invade the field of medicine without medical education.

Another evidence of their insincerity is that they do not want to be licensed as opticians. They are opticians now and probably have legal licenses. They have coined the word optometrist. In New York State they claim that a person who has a state certificate as an optometrist is better able to examine the eyes than the doctors themselves, and several of these fellows have appeared before the Board of Education, when the question of school inspection came up, and said, "Look here, why are you letting doctors examine the eyes of the school children? We are the men to do this work. We know better how to examine the eyes than these doctors do."

The remarkable part of the affair is that the governor signed that bill. They pleaded it before Governor Hughes, and he signed it over the protest of the members of the New York Academy of Ophthalmology.

In Colorado last year Dr. Edward Jackson de-

feated the Optometry Bill by tacking a rider on it, and this rider was nothing except a simple statement of facts defining an optician of this kind honestly and sincerely and squarely, and every man who had been fighting for the Optometry Bill dropped it like a hot cake. He put in an amendment to the effect that nothing in the provisions of this act shall be construed to give the right to any man to use the title of Doctor of Optometry, Doctor of Ophthalmology, D. O., or any other symbol or title, which would lead him to deceive the people that he was other than a licensed optician, giving him no power to use medicine in the treatment of diseases of the eye or to do anything except sell glasses. That rider killed the bill. They got it through the legislature and they had it up for signing, but they dropped it.

In Ohio they got it through both branches of the legislature, but by an earnest appeal on the part of the physicians of Cincinnati, they got Governor Harmon to veto this bill.

Governor Deneen summed up the question when he vetoed the bill in Illinois by pointing out, as is a well known fact, that fully ninety per cent. of the errors of refraction cannot be successfully corrected without the use of a cycloplegic, and there are a great many cases over forty years of age that require oculists of considerable experience before they are able to make a diagnosis of an error of refraction. Governor Deneen said that inasmuch as a cycloplegic was necessary to correct an error of refraction, he could not see why one should give a class of persons the right to do a thing when you denied them the right to use what is necessary for its proper accomplishment (a cycloplegia), and therefore he vetoed the bill.

We intend to bring this matter before the House of Delegates of this association with a view to having a resolution passed condemning this proposed legislation, because it is certainly going to come up. We ought to condemn it in the strongest terms we can use. We should not only condemn it among ourselves but pledge ourselves to go out and work against it, as Dr. Richmond and others have suggested. We should have a resolution sent to every prospective legislator in the State and to the Governor and work continuously to defeat such pernicious legislation.

In conclusion, I want to say that one year is not going to kill it. We have got to keep fighting it.

J. W. Pryor, Lexington: I feel I should say something on this subject because I had some experience in the last legislature with reference to the optometry bill. While I did not take much part in opposing the bill, I know one man who killed that bill, and I think that I should state this to the association, and that man is Dr. J. N. McCormack. (Applause). When the bill was in very great danger of being passed, it was

through his efforts and almost singlehanded that the bill was defeated. He did not have the support of the medical profession nor the support of those who should have given it to him, and the profession did not get back of him as it should have done. Dr. McCormack made some enemies, and came near losing the State Board of Health Bill by it, but through the efforts of a few of us this was corrected. I feel like making that statement to the association.

Louis P. Baltzer, Hickman: I would like to make an explanation to the general practitioner. I suppose a great many of them know, anyway, why we dilate the pupil in young people. It is done for the purpose of overcoming the ciliary muscle or muscle of accommodation.

What does the ciliary muscle do when it contracts? It simply makes the crystalline lens thicker and of course when you change the thickness of this lens it changes the refraction. In young people we generally use Homatropin to paralyze the muscle of accommodation; of course in old people we do not have to use a cycloplegic. You can take most any child with a normal or emmetropic eye and place a minus or near-sighted lens in front of his eye and he will say he can see nicely. Why? Because this minus lens causes a spasm of the muscle of accommodation.

Now if you let the child continue to look through this same lens for a while he will complain of his eye paining him, etc., simply because the muscle of accommodation has been over exerting itself and finally tires. It is nothing unusual for an oculist to run across these cases of young people, who are wearing minus or near-sighted lenses, when they should be using far-sighted or over-sighted lenses.

COUNTY SOCIETY REPORTS

Bell—The Bell County Medical Society held its regular meeting December 8, 1911, at the office of Dr. C. K. Brosheer.

The following members were present: L. L. Robertson, T. H. Curd, W. K. Evans, T. J. Evans, J. P. Edmonds, U. G. Brummett, J. R. Tinsley, C. K. Brashear, T. T. Gibson, of Middlesboro; Ed. Wilson, W. T. Flanagan, J. G. Foley, J. S. Bingham, of Pineville; R. E. Gianinni, O. P. Nuckols, Straight Creek; J. W. Fitzpatrick, Bosworth; F. D. Haston, of Arjay; P. E. Gianinni, Dorothy; J. H. S. Morrison, R. F. Patterson, Cumberland Gap, Tenn.; J. M. Hunnellton, Shawnee, Tenn.; E. N. Harrison, Fork Ridge, Tenn.; J. H. Hendren, Cory; C. L. Clayton, Tejoy, Ky.; L. H. Boone, Day, Ky.; Jacob Schultz, Ligon, Ky.; N. H. Stone, Eagleville, Tenn.; Visitors, Dr. Pennington, Dr. Lock, Barbourville; Dr. Fronisco, Athen, Tenn., Emith Ely.

This being the last meeting of the year our retiring President, C. K. Brosheer, presented the

society with a dinner that is second to none, composed of quail, turkey, salads and a number of other things too numerous to mention, and all expressed themselves as being for Brosheer for President in 1912, but he declined the second term.

The house was called to order by President C. K. Brosheer, this being the business meeting for the year there were no clinical cases nor papers prepared.

A committee was appointed by the President, composed of F. D. Haston, Jacob Schultz, J. G. Foley, for the purpose of drawing up resolutions suggesting some method of remedying the plan upon which contract practice is carried on in the country, hoping to get it on a prescription basis.

Report of the Committee on Medical Examination of School Children in Bell county, carried over. This committee is composed of Drs. Robertson, Edmonds and Brosheer.

Report of the Committee on County and Municipal Practice, carried over.

B. E. Gianinni, Straight Creek, P. E. Gianinni, Dorothy, transferred from Whitley county as members of our society.

N. H. Stone, Eagleville, Tenn., elected member of our society, after being reported favorably by the Board of Censors.

Motion made and carried that the Secretary get in communication with the Anti-Tuberculosis Association of Louisville in regard to the Anti-Tuberculosis car visiting this city under the auspices of the Civic Club through the medical society.

J. H. Hendron, of Cory, elected President for 1912; W. K. Evans, Middlesboro, Vice President; O. P. Nuckols, Pineville, Secretary; U. G. Brummett, Treasurer; Jacob Schultz, Member Board of Censors for three years.

Our efforts this year have been to get every legal practicing physician in the county a member of our society, and the results of our efforts are an increase from 26 in 1910 to 41 on our roll at the present time, leaving five non-members yet in the county, all of whom have expressed themselves as intending to join us. We regret to close the year without them on our roll.

The society adjourned to meet in Pineville, January 12, 1912, with the new officers presiding.

T. T. GIBSON, Secretary.

Carlisle—The Carlisle County Medical Society met at Bardwell, December 5, 1911, with President Lamkin in the chair.

Members present: G. W. Payne, T. T. Crouch, R. C. Burrow, T. J. Marshall, C. D. Shelbourne, T. L. Lamkin, W. Z. Jackson, Jno. R. Owen, J. F. Dunn, W. L. Mosby and Wm. Graves.

T. J. Marshall read a paper on "Acute Tonsillitis." It was a practical and up-to-date paper. He favored the use of salicylates in most all cases.

W. Z. Jackson and **J. F. Dunn** favored the use of nitrate of silver solution to the tonsils.

G. W. Payne punctures the tonsils in several places with a sharp lance. He also makes applications of tannate of glycerine.

H. T. Crouch, **T. L. Lamkin** and **Wm. Graves** took an active part in the discussion, which was closed by **T. J. Marshall**.

The next on the program was **W. Z. Jackson's** paper on "The Care of Premature Children." It was a very instructive paper. He emphasized three points, viz: First, Uniform temperature; Second, Proper nutrition; Third, Amount of handling, which should be reduced to a minimum. He also believes in every instance you should wait till cord ceases to pulsate before ligating. He reported a case of twins born at six and a half months, weighing four pounds each. Mothers didn't have any milk. Kept temperature under the cover at 90-95 degrees, fed on Eagle Brand condensed milk, comparatively no handling and careful nursing. One of them died in about three months. The other living and doing well and is about six months of age.

The society adjourned for dinner.

Reassembled at 1:30 o'clock and after a free discussion of Dr. Jackson's paper, was closed by the writer.

W. L. Mosby read an interesting paper on "Uterine Displacements." It was ably discussed by most all present.

R. C. Burrow recommended vaginal tampons soaked in salts-water and glycerine, which he thinks will remove the engorgement of uterus.

C. D. Shelbourne says berberine sulphate in 1-6 grain doses will remove the enlargement of the womb.

As Dr. Mosby had to leave, Dr. Crouch closed the discussion, and recommended pregnancy.

Last but not least was **President Lamkin's** farewell address. "The Prophylaxis of Specific Diseases by Legislation." He is highly in favor of quarantining. The paper was well prepared and contained some real important points, which will appear in the State Journal. There was a unanimous vote to have his paper published in the county paper, giving the editor the right to change certain phrases as would be suitable for the public to read.

By order of the society, we will meet monthly in the future.

Election of officers resulted as follows: President, **T. J. Marshall**; Vice President, **C. D. Shelbourne**; Secretary, **J. F. Dunn**; Treasurer, **W. Z. Jackson**; Censor, **W. E. Gholson**.

After installation, **R. C. Burrow** was elected Delegate to the State Meeting.

The next meeting will be held at Arlington, on the 2nd of January, 1912.

J. F. DUNN, Secretary.

Christian—The Christian County Medical Society met in the City Courtroom, Hopkinsville,

Ky., Tuesday, December 19th, 1911, with President Wright in the chair.

The members present were **O. E. Wright**, **J. L. Barker**, **J. W. Harned**, **F. M. Stites**, **F. H. Bassett**, **O. L. Barnes**, **G. W. Lacy**, **S. H. Williams**, **T. W. Perkins**, **B. A. Caudle**, **J. Paul Keith**, **Austin Bell**, **E. L. Gates**, **H. C. Beazley**, **A. H. Edwards**, **W. A. Lackey**, **D. H. Erkiletian**, **J. H. Rice** and **W. S. Sandbach**, and **Walter Bartlett**, of Elkton.

The minutes of the last meeting were read and approved.

J. H. Rice and **Walter Bartlett** presented a very interesting clinical case, which was examined and discussed by nearly every one present. The diagnosis was at question, but finally decided it was specific and "606" was advised. The doctors are to report at the next meeting.

This being the business meeting of the year, the following officers were elected for 1912:

President, **J. L. Barker**; Vice President, **S. H. Williams**; Secretary-Treasurer, **W. S. Sandbach**; Censor, **T. W. Perkins**; Delegate to State Meeting, **W. S. Sandbach**; Alternate, **W. S. Lackey**.

Drs. Barker, **Lackey** and **Sandbach** were appointed as a committee to form a program for the next year.

There being no further business, we adjourned to meet the third Tuesday in January,

W. S. SANDBACH, Secretary.

Davies—The Davies County Medical Society met at the City Hall, Owensboro, on December 19th, with the President, **Ed. Barr**, presiding, and thirty-six members present.

J. Glahn read a very interesting and instructive paper on the old Transylvania University.

P. D. Gillim read a paper on the "Use of Salvarsan in Syphilis." He had given thirteen injections in as many cases. Reported no bad results, but some very good ones, and a few neutral. He is enthusiastic about the remedy, and made a good and interesting talk.

J. B. McGary reported several cases in which he had used it. He and **Dr. J. A. Kirk**, who spoke next, hoped for great results from the proper use of "606".

The paper was further discussed by **Drs. McKenney**, **Strother**, **Rash**, **Barnhill**, **Stirman** and **McDonald**.

Officers for the ensuing year were elected as follows: **W. E. Irvin**, Owensboro, President; **Ben F. Tiehenor**, Pleasant Ridge, Vice President;

As the Secretary-Treasurer had reported \$119.64 in the treasury, he was re-elected.

Sensor, **F. A. Miller**, Owensboro; Delegate **C. H. Todd**, Owensboro.

J. W. Ellis and **D. M. Griffith** made very good and interesting reports of the State Meeting, and were given a vote of thanks.

The city physicians set an elaborate banquet at which **Dr. D. M. Griffith** in his felicitous style

acted as toastmaster, and J. W. Ellis and E. D. Turner made good talks.

J. J. RODMAN, Secretary.

Franklin—The Franklin County Medical Society met December 4, at 2 p. m., with President M. C. Darnell, at his country home in social session and enjoyed a most delicious banquet.

The business session proceeded the banquet and besides the routine business, the discussion of "Euthanasia," was discussed from a medical, moral and unprecedented standpoint. Much diversity of opinion was expressed but the consensus of opinion was in the negative.

H. S. Keller was appointed to prepare a paper for next meeting, to select a theme on some line in connection with the State Board of Health, of which body he is an active member.

U. V. Williams proposed for submission to the society, whether it would be expedient in the lethal condition of our society to procure "Euthanasia" by a hypodermic of morphine and let it die painlessly or to attempt to revive it by the use of nitroglycerine and "Con-sel-sir." a-la Charley White-Moon."

It was finally decided to give the "Sick Man" one more chance to come around and elect officers for 1912, which was then had resulting as follows:

President, Flora W. Mastin, Frankfort; Vice President, H. S. Keller, Frankfort; Secretary, and Treasurer, U. V. Williams, Frankfort; Delegate to State Meeting, U. V. Williams; Alternate, H. S. Keller; Censor and Referee to be appointed in January by the incoming President.

After which adjournment was taken to January 1st, 1912, in the office of Drs. Williams & Mastin, Frankfort.

U. V. Williams, Secretary.

Lincoln—The Lincoln County Medical Society met in Dr. Peyton's office, December 12, 1911, and elected the following officers:

President, W. B. O'Bannon; Vice President, W. N. Craig; Secretary and Treasurer, M. M. Phillips; Delegate, T. H. Singleton; Alternate, J. A. Harmon; Board of Censors: E. J. Brown, T. F. Jones, W. D. Laswell, and W. J. Childers.

W. B. O'Bannon read an excellent paper on "Syphilis," and was discussed by all present.

The Committee on Program reported that during the year every member of the society would be placed on the program.

Papers for next meeting will be prepared by Drs. Singleton, Brown and Carpenter.

M. M. Phillips, Secretary.

Knox—The Knox County Medical Society met in regular session in the office of G. H. Albright, the secretary, at 1 o'clock with full stomach and empty pocket-hooks. We made this a general business meeting, without any regular program. After which we elected the following officers for

the ensuing year: President, Wm. Burnside, Barbourville; Vice President, F. R. Burton, Flat Lick; Secretary-Treasurer, G. H. Albright, Barbourville.

Each member present pledged their full support in assisting the President and Secretary in making these meetings instructive and with a full attendance at each meeting.

G. H. ALBRIGHT, Secretary.

Pendleton—The Pendleton County Medical Society met at the Day House, in Falmouth, Wednesday, December 13, 1911, with the following members present: Blackerby, Caldwell, Clark, Ellis, Hopkins, McKenney, Nichols, John E. Wilson, J. Ed Wilson, Woolery, W. H. Yelton.

The meeting was called to order with President Hopkins in the chair, and after roll call, and a reading of the journal of the last meeting, we proceeded to the business of the day. Under new business, the following were elected officers for the next year: P. N. Blackerby, President; O. W. Brown, Vice President; W. A. McKenney, Secretary and Treasurer; K. B. Woolery, Assistant Secretary and Treasurer; J. F. Daugherty, Delegate to the State Meeting for two years; J. A. Caldwell, Alternate; H. C. Clark elected member of the Board of Censors. Committee on Program: Drs. Blackerby, Brown, McKenney, Clark, J. Ed Wilson; Committee on Publicity, K. B. Woolery, W. H. Yelton, Caldwell; Public Health, Daugherty, Beckett, Nichols; Critic John E. Wilson.

After the usual report of clinical cases, and their discussion, the noon hour had arrived and we adjourned for dinner.

Afternoon Session.—First was a deferred paper by **W. A. McKenney**, subject, "Acquired Deformities of Children." Discussion was opened by **J. A. Caldwell**, after which several members discussed the paper.

This closed the business for the day and the rest of the time was given over to a social good time.

We have had a splendid year for our society, and we can see the many benefits that it is to us, and we are more thoroughly imbued with the spirit of fraternalism than ever before. While we have not grown in numbers, we have all the material in the society that it is possible to get, there are a superannuated member or two of the profession in the county but they are not trying to do anything, and considering that some of our best members live in another county, and some of those in our own county have to drive fifteen miles to get to the place of meeting, I think our average attendance of 12 1-2 out of 21 members in the society is hard to beat. Wishing the society in the State and our Journal a merry Christmas and a Happy New Year. And may we all begin the new year with a firmer resolve to be better physicians than we have in the past.

W. A. McKENNEY, Secretary. Google

Washington—The Washington County Medical Society met in the courthouse in Springfield on Dec 20th, with the following physicians present: R. C. McChord, Lebanon; W. W. Ray, M. W. Hyatt, W. E. Crume, W. R. Thompson, W. S. Gabhart and J. H. Hopper, of this county. Vice President Hyatt was in the chair.

The minutes of last meeting were read and approved.

R. C. McChord, our Councilor, having been invited to read a paper before this society, was present, and took for his subject, "The Open Treatment of Fractures of the Shafts of Long Bones." This was an excellent paper and it drew forth a great deal of discussion, and many questions. We are always more than glad to have Dr. McChord with us and we always are profited by his essays and good advice.

W. S. Gabhart reported a case of "Peritonitis" which ran a very irregular course. The interesting points were the cause and diagnosis. Every one present entered into the discussion at some length.

W. W. Ray reported a case of erysipelas of a child of three months which covered almost the entire body starting on the vulva. Large doses of anti-streptococcic serum were used with no results. The consultant noticing an article by a German physician in the Therapeutic Gazette, recommending antitoxin (diphtheritic) decided as a last resort to try it, though illogical. Two doses of several thousand units were injected. A change was noted for the better in twelve to eighteen hours and in forty-eight hours there was a very decided improvement.

The following officers were elected for the year 1912: W. E. Crume, President; W. S. Gabhart, Vice President; J. H. Hopper, Secretary and Treasurer; M. W. Hyatt Delegate, with W. S. Gabhart as alternate.

W. R. Thompson was appointed Censor for one year and Dr. M. W. Hyatt for three years.

J. H. HOPPER, Secretary.

Whitley—The Whitley County Medical Society met in Williamsburg, at the office of Drs. Ellison and Croley, December 12th, with the following members present: J. D. Adkins, S. S. Brown, L. B. Croley, C. G. Ellison, E. S. Moss, A. A. Richardson, J. H. Parker, L. Sproule, S. Sullivan, L. O. Smith, S. B. Snyder and M. W. Steele, and District Councilor J. S. Lock, of Barbourville.

After some delay awaiting the arrival of B. F. Tye and L. L. Terrell, President and Secretary, who arrived later having been unavoidably delayed, the meeting was called to order by Vice President S. S. Brown, who appointed C. G. Ellison acting secretary.

J. S. Lock, who having recently been appointed by the Rockefeller Institute to investigate the hookworm disease in Southeastern Kentucky, was called upon for an address. He stated that

there had been several cases diagnosed in the district, and following a very able discourse on the subject, he urged the cooperation of all the doctors in his research work, explaining in detail the method of obtaining and mailing specimens to the State Bacteriologist. Drs. Moss, Parker and others followed with interesting talks on the subject in a general way, with the conclusion that some relation might be found between that disease and pellagra.

The society expressed its appreciation of the action of the Rockefeller Institute, and of the honor conferred upon our sister county, Knox, in the appointment of Dr. Lock to do research work.

Officers for the ensuing year were elected as follows:

S. S. Brown, Mountain Ash, President; C. G. Ellison, Williamsburg, Vice President; M. W. Steele, Corbin, Secretary and Treasurer; L. B. Croley, Williamsburg, Censor, making the Board of Censors for the ensuing year: Drs. C. A. Moss, J. D. Adkins and L. B. Croley, all of Williamsburg.

Thursday, February 1st, was chosen as the time for the next meeting.

E. S. Moss, on behalf of the Williamsburg doctors, invited the society to meet at Williamsburg, promising entertainment to dinner to all members and visiting doctors. We trust that many will avail themselves of the hospitality of those big hearted medical men of Williamsburg. A good scientific program will be rendered.

M. W. STEELE, Secretary.

BOOK REVIEWS

Practical Cystoscopy and the Diagnosis of Surgical Diseases of the Kidneys and Urinary Bladder.—By Paul M. Pileher, M. D., Consulting Surgeon to the Eastern Long Island Hospital. Octavo of 398 pages, with 233 illustrations, 29 in colors. Philadelphia and London: W. B. Saunders Company, 1911. Cloth, \$5.50 net.

During the past ten years the study of diseases of the kidneys, ureters and urinary bladder have been greatly stimulated by the development of the newer methods of diagnosis. Of these the cystoscope and the urethral catheter are undoubtedly the most important.

The indications for the use of the cystoscope are becoming more generally known, and the ease with which a simple cystoscopic examination of the bladder can be made has led to its early employment in appropriate cases. The present volume considers the indications for cystoscopy, and outlines its technique in the minutest detail, describing the instruments used, and how far to use them.

A notable feature of the work are the numerous illustrations, both plain and in colors, which assist greatly in conveying to the reader an adequate impression of the appearance of the bladder in the various pathological conditions involving it.

A FEW REASONS WHY DRUGS DO NOT CURE INDIGESTION.

By HUGH N. LEAVELL, Louisville.

We might transpose this sentence and express it thus: "A few cases of indigestion which drugs cannot cure"; for we must acknowledge that drugs cannot do all we claim for them.

Indigestion is but a symptom of a pathological condition, or a change in the secretions; therefore, we may divide cases of indigestion into two general classes, as follows:

1. Indigestion superinduced by changes in secretions.

2. Indigestion superinduced by organic changes in the stomach or some remote organ.

There are a great many conditions of secretion over which medicines have but little influence. Cases are on record where persons have become gray-haired in a single night, due to changes in secretions furnished to the hair follicles. We know that the secretions thrown out by the stomach are markedly modified by habits of life, time of taking food, and many other conditions, too numerous to mention. The gastric secretions must change as our diet changes or we suffer from indigestion. The character of the blood current may influence digestion and assimilation so that the worst symptoms of indigestion which we have may supervene. Passive congestion of the stomach superinduced by a liver disorder, or by Bright's disease, is an instance in point. The physician who attempts to keep up with the whimsicalities of every stomach must have the lamp of Aladdin to illuminate his field of vision; or, if he be so astute as to recognize

causes for every symptom, the juggling with materia medica which would be thus necessitated, would be well-nigh impossible. Take, for example, the most common condition of hyperchlorhydria. Antacids but modify the acids in the stomach, so that the intestines, by virtue of the modification of these acids, are not properly stimulated and we superimpose upon what was once a purely stomacheic condition, an intestinal one which is far more serious. Physiologists tell us of the marked correlation which exists between the digestive secretions. We recognize that the normal secretion of the salivary glands is essential in the proper stimulation of the gastric juice, and the gastric juice, in turn, must be of a proper consistency in order to stimulate the activities of the liver, or the *succus entericus*. The modification of any one of these secretions may influence digestion anywhere from the oesophagus to the colon. We must depend at all times upon the proper correlation of these digestive juices in order to maintain normal digestive functions anywhere in the digestive tract. As yet we have no drug which can supply the proper stimulating force for cell activity. The class of drugs called digestants are only of value as extraneous remedies, having no stimulating effect whatever upon cell activity, but rather having a tendency to inhibit the activity of the cells by reason of the fact that they do for the organs work which the organs themselves should do. This point is well emphasized in the use of peptonized foods, the individual being able to take care of a much higher percentage of proteids, or other foods, by reason of their having been predigested. If we use drugs such as some of the stomachics, we merely increase the flow of the gastric juice beyond the normal, and if this be in excess,

it may over-stimulate the organs farther along the digestive tract, and overstimulation will sooner of later result in a reaction which will mean lessened secretion and consequent indigestion. I do not wish to be put down as a therapeutic nihilist, but I do believe that drugs which overstimulate, or drugs which lessen the gastric secretions below the normal, cannot do other than harm. As a temporary expediency they are of some benefit, but does this necessarily mean a cure of the condition? Therefore, we must say again, that drugs which have for their function an increase of secretion, or a diminution of secretion, ultimately work along a pathological line. We know the tendency to the production of gastric ulcer by hyperacidity of the gastric juice, and we often see symptoms of marked indigestion produced by *nux vomica* in increasing the flow of the gastric juice.

The opposite condition, anacidity, such as is found in cancer of the stomach, is treated by supplying the material which is lacking—namely, hydrochloric acid, and we find that this, sooner or later, has a tendency to increase the growth of the pathological process.

I think it can be safely asserted that we have not yet reached the point where a gastric analysis will furnish us all the points which we need in making our therapeutic attack, and one of the reasons for this seems to be the variability of the gastric juices. We cannot doubt that, as a confirmatory measure, considered in connection with the history obtained as to previous attacks, etc., gastric analysis may often furnish us a clue as to the proper procedure, but even then our therapeutic resources are limited so far as the secretions are concerned.

As to the second proposition—indigestion superinduced by organic changes in the stomach or some remote organ—I have no doubt that there are many present who are constantly finding cases of gall-bladder disease, appendicular troubles, lesions in the sigmoid, etc., by which the digestive apparatus is modified or influenced. I also have no doubt that many here present can cite examples of chronic appendicitis giving rise to hyperchlorhydria. It is surprising to see how many cases of indigestion have a distinct pathological lesion as a causative factor. Those who will take the trouble to examine the right iliac region, the hepatic region, and the region of the sigmoid, will be surprised to find how many times cases of chronic indigestion will present tenderness upon palpation in either of these regions. I am sure that no one would think, for a single moment, of curing appendicitis or gall-stones, for instance, by any known method of drug medication. It took a good many years for the profession to come to recognize appendicitis, for example, as a

purely surgical disease, and at the present time there is a remarkable trend in the same direction with respect to gall-bladder disease and ulcer of the stomach. I do not mean to say that gall-bladders should be removed in the same way that appendices are now removed, but that drainage of gall-bladders which have been the subject of cholecystitis or gallstones will have a marked effect in the alleviation of many digestive disturbances which have been superinduced by pancreatic disease as well as hepatic disorders. It is unnecessary to report many cases to illustrate the inefficiency of drugs and the value of operation for the relief of many of these patients, but one case with which I recently came in contact will be sufficient, I think, to demonstrate that drugs are of little avail.

Mr. H., 65 years of age, had an attack of gall-bladder disease twenty years ago. At that time no stones were diagnosed. After this attack he did not see a physician for a good many years, except for occasional attacks of grippe, so-called. I saw him for the first time six weeks ago, with a history of having suffered for several months with what he thought was appendicitis, but in the fear that some one would advocate an operation, he deferred consulting a physician. He also complained of dragging pains all over the right side. He was a man who had never drank to excess, and who was very moderate in his eating, but his habits were sedentary. An examination of his urine was made, but no pathological lesion was found other than an indicanuria. He gave a history of his bowels having acted daily, but occasionally he had to use a mild laxative. He sometimes suffered with a burning sensation in his stomach a few hours after eating, which was possibly due to an hyperchlorhydria. This was relieved by the ingestion of food.

Physical examination revealed marked tenderness over the hepatic region, extending well down toward the appendicular region. He had a temperature of 102°. After mild purgation the acute symptoms subsided, and were followed by marked anorexia and a good deal of flatulency. After about two weeks in bed upon a liquid diet and intestinal antiseptics, during which time he made no progress, he rather suddenly developed symptoms of intestinal obstruction. Thinking this was probably due to adhesions in the region of the gall-bladder, he was given eserine hypodermically for two or three days, hoping thereby to lessen the excessive gas formation and possibly allow the bowel to straighten out its own kink, but as he did not get relief from his symptoms he was taken to the infirmary and operated upon.

Upon opening the abdomen a marked amount of fluid was drained off, and upon fur-

ther exploration the tumor which I herewith present was found. Recognizing the hopelessness of the case, the abdomen was simply closed. He rapidly recovered from the effects of the operative procedure, but died two days later with symptoms of asthenia.

After his death, with the permission of the family, I removed this mass which, upon examination by Dr. Baldauf, proved to be a metastatic carcinoma of the omentum. This condition has for its starting point, the gallbladder, and had he been treated twenty years ago as is now advocated, the chances are that he would have been saved many years of suffering, and his life prolonged.

Primary cancer of the omentum is extremely rare, and as a metastatic growth I am sure it is not common. Therefore this case may be of some interest. It also demonstrates my second proposition—that indigestions are often superinduced by pathological conditions upon which drugs can have no effect.

In closing, I wish to state again that, having no drugs by which we can stimulate normal cell activity, and no drugs by which we can influence the secretion of one organ except to the detriment of another, or the production of a pathological lesion in the organ which is stimulated, therefore, we can safely assert that medicines must necessarily play a minor role in the cure of indigestion. So far as pathological lesions are concerned, they can have absolutely no effect for the reason that a lesion which is sufficient to cause enlargement of an organ may sooner or later, by metastasis, affect other organs, or by throwing out numberless adhesions, may produce acute intestinal obstruction.

DISCUSSION.

Wm. H. Wathen: I do not know of a more timely subject than that which Dr. Leavell chose for his paper, because we are now going through an evolutionary process in connection with the treatment of this condition—from the functional idea to the organic belief. I will not consume your time by reciting the numerous cases of chronic dyspepsia that I have cured by operation for organic diseases of the stomach, of the gallbladder and of the appendix. We frequently have indigestion from arteriosclerosis, locomotor ataxia, and other conditions, the stomach symptoms being only a manifestation of the organic disease. I will have time in this discussion to refer to only three of the organic lesions which occur in the stomach, in the gallbladder and in the appendix.

We will find nothing so beautifully written in the present age as the classic descriptions of dyspepsia given so many years ago by Watson, Johnson, Abercrombie, Abernathy, and Trouseau, but they all believed that these dyspepsias were simply functional disorders, and treated

them accordingly. Now we seem to be going to the other extreme, which is due to the progress of abdominal surgery, and to the fact that most of these old cases of chronic dyspepsia, that have been treated for many years perhaps, by the internists, are never cured; or, rather, are cured half a dozen times but always with recurrence. We remove gallstones from the gallbladder, or separate adhesions of the gallbladder and drain it, and these cases are cured. We see patients who have been treated for from two to twenty-five years by internists, who have pain coming on two to four hours after eating, and continuing until food is taken, which relieves the pain. They get a little better under medicinal treatment directed to the stomach, and very often they will get better without any treatment at all. They are better in warm and dry weather, and worse in cold or wet weather. Sometimes they will feel entirely well for several months, but recurrence will always take place. Such cases are never cured until operated upon for chronic, calloused ulcer of the duodenum. Other cases, not so marked, are those where there is a chronic ulcer in the pyloric end, or body of the stomach. These also are never cured until surgery is done. There are still other cases where we have indigestion coming and going, or possibly continuing for several months at a time, in which the pain is worse just a few minutes after eating. These are never cured except by operation, revealing some pathology of the gallbladder. There are other cases where we have indigestion coming on and lasting continuously, sometimes better and sometimes worse, the pain usually increasing soon after eating. Such cases will not be cured until we have removed the appendix. This organ may not be greatly diseased, but there have been pathologic changes which will not get well, and the patient will not get well of dyspepsia until the appendix is removed. Operative work has shown that in from 30 to 40 per cent. of cases of chronic ulcer of the stomach or duodenum, a manifestly diseased appendix will be found which has antedated the ulcer, showing that there is apparently some relation between the origin of ulcers in the stomach and duodenum and appendicitis.

In conclusion, I will say that originally most of these cases were considered to be functional, but every day we are excluding some so-called functional disorder and showing that it has an organic pathology. I make this prediction; that within the next ten years, at least 90 per cent. of all cases of chronic dyspepsia, that have in the past been treated as functional, will be proven positively to have an organic basis, and will be relieved by proper surgical procedure, except cases where the dyspepsia is but the stomach expression of cardiac insufficiency, arteriosclerosis, chronic nephritis, locomotor ataxia, etc.

Bernard Asman: Indigestion is very often a

symptom of disease conditions outside of the stomach. Dr. Wathen has very properly called our attention to the fact that many cases of indigestion are cured by operations for disease of the gall bladder, appendix, etc. I feel that I must also call attention to the fact that many cases of indigestion are relieved by the removal of piles. No less an authority than Tuttle in his excellent text book upon diseases of the rectum, in classifying the vaguer symptoms suggesting the necessity for an examination of the rectum, puts indigestion at the head of the list; and it is unquestionably a fact that, very often, after operation for the removal of piles, or some other ano-rectal disease, a patient who has been a sufferer from indigestion for many years, will, in a comparatively short time, be entirely relieved of his indigestion.

Bernard J. O'Connor: It would appear that after all these specialists are through with us, we will not have an organ left in the body. There is no question in the world that indigestion may spring from numerous sources, but one would gather from the discussion this evening that indigestion is always a surgical condition. I think this is a mistake. As to Dr. Wathen's prediction, it would appear that he can see farther into the future than most of us. Of course, there are numerous abdominal conditions which may cause reflex stomach symptoms, but there are other diseases which, by toxicemic disturbances, may give rise to manifestations of stomach trouble. Of the latter the one which is to my mind of the most importance, is tuberculosis. Tubercular conditions are almost invariably accompanied by symptoms of indigestion. Therefore, in every case in which we find these symptoms, I think we should take the temperature and examine the chest, as well as the gallbladder, duodenum, rectum, etc. Nephritis could also be cited as another common cause.

In connection with the case reported by the essayist, he mentioned that the patient had an indicanuria. Indicanuria is an exceedingly important symptom and one which the majority of practitioners do not appreciate. It is not always an indication of intestinal obstruction, constipation, proteid indigestion, and like conditions, but we invariably find it present in suppurative conditions. No matter where the suppuration may be located, the absorption of the toxic substance will produce an indicanuria. The same is true of malignant conditions. In Dr. Leavell's case, the patient had a carcinoma apparently of some portion of the intestinal tract. If this growth was of the cylindrical-cell type, it unquestionably originated somewhere in the intestinal tract, or in the gall-bladder.

E. S. Allen: I would like to ask the essayist whether or not there were any adhesions between the gallbladder and omentum? I would say that this omental growth is merely an extension or transplantation of the carcinomatous cells from

the gallbladder. We know that it is impossible to have a primary carcinoma of the omentum, or peritoneum, or any structure of mesoblastic origin, and when they develop in these structures it must be due to transplantation.

I think Dr. Leavell, in referring to cases of chronic indigestion which need operation, had in mind those cases which have continued over a long period of time, and which have not been relieved by rest, diet and medication; that such cases must have some organic lesion which is responsible for the trouble, and I think that is generally the case.

B. F. Zimmerman: I think in discussing this or any other subject, we are apt to regard it from our own particular viewpoint; that is, the rectal specialist is prone to attribute disorders of digestion to some condition of the rectum, the eye specialist to errors of refraction, the gynecologist to the uterus or its adnexa, and so on. We have here a group of conditions in some of which the symptoms are directly due to a pathologic lesion of the digestive tract; others where they are in the nature of reflex phenomena. It seems to me to be rather stretching it a little to say that ninety-nine out of every hundred cases of chronic digestive disturbance are due to some surgical condition, abdominal or otherwise. It will be a very difficult matter to convince any man who has had considerable experience in general practice that such is the case. I grant you that disease of the gallbladder and appendix, hemorrhoids, uterine displacements, disease of the tubes and ovaries, etc., may give rise to symptoms of indigestion. Furthermore, we may have lesions of other parts of the body, not of a surgical nature, which may give rise to just as pronounced symptoms of indigestion as any surgical condition of the abdomen. Any one who has had any experience in general practice recognizes the relationship between organic lesions of the heart, or thoracic conditions, and digestive disturbance, renal conditions and digestive disturbance, and, above all, affections of the central nervous system, either organic or so-called functional, which may give rise to a multitude of digestive disturbances. Therefore, I think we should not go off "half-cooked" as it were. We should consider every condition which may, directly or reflexly, give rise to these digestive disturbances before we arrive at the conclusion that surgery is the panacea for all of these ills.

W. A. Jenkins: I should not speak of this subject from the standpoint of the internist, and yet, if I say anything at all, it will have to be from that standpoint. We have been told to-night that drugs cannot influence physiological cells, and likewise that the only permanent relief for chronic indigestion is the use of the knife, and I feel that there is very little left for me to say. Fortunately, however, as shown by the other speakers, there are men here to-night who do not

agree with the essayist. Nevertheless, I take it that there are some lessons for the internist to gain from this paper and discussion. Whether these gentlemen be right or wrong in their premises, the fact remains that we are not doing as much as we ought to do along this line. Perhaps we are not recognizing this condition as often as we should, and perhaps we have not an appropriate treatment for it, and, that being the case, it behooves us to take ourselves back, review the ground and adopt different, newer and better methods; or, at least, to make a careful, scientific search for other methods or arriving at conclusions in these obscure cases. I think that modern inventions for ascertaining various facts which have a bearing upon disease conditions, together with more careful and thorough methods of physical diagnosis, are going to help us a good deal, enabling us to make diagnosis by exclusion, sticking to one hypothesis until it has been proven to be right or wrong, and not discarding it until disproven, using every means at our disposal for determining these conditions. This we will have to do, and it will enable us to prove whether or not drugs are absolutely useless and the knife is the only remedy.

No less an authority than Von Noorden made the statement that the internist had a new field in the study of metabolism and that some startling results were to be obtained along the line of internal medicine. Such men as Voit, Salskowsky and Von Noorden himself have been doing a great deal of work along the line of physiological chemistry and metabolism. Again, the work done by Cannon has enabled us to interrogate the pancreas and liver and see what they are doing by examination of the feces. If we adopt the newer studies of metabolism and try to make progress along this line, we may some time get to the point where we can get these cases in the pre-surgical stage, which is the ideal thing to do. The surgeons say that they cure these cases by surgical methods, but I have an idea that many of them are not permanently cured, and I believe there are other internists in this room that have had the same experience I have. I have had these obscure cases in which the conclusion was reached that the gallbladder ought to be opened and drained, and they were referred to the surgeon for operation. The individual seems to improve promptly; there is apparently an almost miraculous change for the better, but in the course of a year or two there is a recurrence of the symptoms and the patient is worse than before. I have under observation a woman who was operated upon eighteen months ago, and she is getting back into identically the same condition as before the operation. She is having the same attacks and they are quite as severe. Perhaps if we, as internists, knew the proper steps to take in such cases as this, we might prevent them from becoming surgical. I know of other cases which

have followed the same general course. Therefore, surgery is not the entire nor the best solution of the problem; we must acknowledge that there is a field for the internist and therapist. They are coming into their own, and therapeutic measures, whether drugs, antitoxins, vaccines, or what-not, are going to become of more value than ever before. There will always be a place in the practice of medicine for the internist.

F. C. Askenstedt: While many cases of indigestion are no doubt due to causes outside of the stomach, still it is a fact that treatment directed to the stomach will satisfactorily palliate the majority of cases of indigestion that come to us as internists. The surgeon finds that many cases of indigestion are associated with appendicitis, gallstones, etc., and if the patient improves after an operation he concludes that the indigestion was due to the surgical condition, but he has no means of knowing how many cases are relieved, or cured, by the internist without surgical measures.

I was delighted with this paper. I do not know of a single point made by the essayist to which I would take exception. One point that I would particularly emphasize is the abuse of drugs. Perhaps, being a homeopath, I know more about that than the rest of you, because it is those cases that have been drugged and drugged until the stomach has rebelled that come into our hands for gentler treatment. There is no doubt in my mind that a great many cases of indigestion are induced by abuse of the function of the stomach; that is, by abnormal eating and drinking; some swallowing their food half masticated, others bolting it with enormous quantities of liquids. Some persons have the idea that the more water they drink, the better their digestion.

Another point to which I wish to call attention is the motor power of the stomach. Most cases of indigestion are produced by insufficiency of the motor power, and this is a condition that we are apt to overlook. In all of these stomach cases we should ascertain, by gastric analysis, not only the increase or deficiency of hydrochloric acid, but we should determine the position of the stomach and its motor power. When the stomach retains the food for an abnormally long time, fermentation, and sometimes putrefaction, takes place, causing a sense of distension, eructation, and sour risings. In other cases, although there may be a diminished amount of hydrochloric acid, and an actual gastritis, the patient may not complain at all, because the motor power of the stomach is increased and the food is passed into the intestine before digestion is completed. In treating these cases, therefore, we should adjust the stomach to the condition that is present, and that alone will do much toward relieving these patients. In cases where the motor power is diminished it is a good plan to give small meals at frequent intervals; not

dry food, as is sometimes recommended, but mushy food, half solid and half liquid. By feeding the patient every hour or two, these cases of gastric motor insufficiency will often be greatly alleviated.

We should not attempt to treat any case of stomach trouble without first making a very careful analysis of the urine. The presence of indican in the urine indicates positively that putrefaction is taking place in the intestines, and while some constitutions can take care of this excessive indicanuria, many others are not able to do so. Most of the toxins are evidently of protein character and those persons who are able to stand this amount of indican in the system are always on the brink of pathology and there is always imminent danger of the system breaking down.

The acidity of the urine should be determined, not only qualitatively, but quantitatively, and where there is a hyperchlohydria we should endeavor to palliate it by giving an alkali if the acidity of the urine be high, but where a neutral or alkaline reaction obtains there is a possibility of the blood becoming over-alkalinized, and the urine becoming strongly alkaline, and renal calculus may result.

J. D. Hamilton: I have been very much interested in Dr. Leavell's paper. We are bound to recognize that, as internists, we have not always made our diagnoses positive, and to administer drugs, with an imperfect diagnosis, is bound to bring about unsatisfactory results, but to my mind it does not prove that drugs are absolutely useless. The fact that we have not thoroughly understood the pathological condition present, nor the therapeutic and physiological action of the medicines used, is not an indication that drugs are inert and useless in such conditions, nor, as has been held by surgeons present this evening, that they can be cured by surgery. I believe that when we come to understand more about the pathological conditions we are dealing with, we will find that many of these cases are unquestionably organic, and not functional, but it does not necessarily follow that because it is an organic lesion it must be treated surgically. As has been brought out by Dr. Jenkins, the field of metabolism is broad and as yet practically uncultivated. The field is open to us as internists, but we have not cultivated it, and we should not get jealous of the surgeon because he has been doing better and more scientific work along these lines.

I can indorse everything that the essayist has said except that drugs have no effect whatever. If we know how and when to use drugs, and for what we are giving them, we will get good results, but in the hands of a man who does not know how to use them, they will do harm. Also, if the surgeon puts his operating paraphernalia in the hands of a man who does not know how to use it, he will do more harm than good.

John Karagiozian: Of course, I stand with

the general practitioners upon this question. I wish to mention only one or two points in connection with this subject. Being from a foreign country I notice the difference between the customs of this country and others. This is a young nation and it has an enormous appetite for various things. One is for food. American people like to eat all the time, whether they have an appetite or not, and whether the stomach is sick or well. I asked one of my friends at meal time whether he had an appetite, and he replied—"No; I have no appetite, but I have the habit." American people have the habit of eating and there is no rest for the stomach, and when the stomach breaks down and they have no appetite, they go to the doctor for a prescription for some medicine to give them an appetite. All this leads to various conditions, such as heart trouble, rheumatism, etc. In my country the people very seldom suffer from indigestion. They eat only twice a day. They go to their work in the morning without eating anything, and just before noon they eat a very light meal. The evening meal is really the only meal they have, and by that time they are hungry, the body desires food, and they have an enormous appetite, but not enough to destroy their constitution. When people have dyspepsia they should give the stomach rest; they should not eat until they have an appetite—until Nature calls for it. I have never seen the people of any other country break down at the age of 40 or 45 as they do here, and at first I could not understand the cause of it. The people of this country have an immense appetite for sexual relations, and that will break down the people of any nation. The nervous system has a very intimate connection with the stomach, and when the nervous system breaks down the stomach suffers. We can regulate this somewhat if we would not be ashamed to question our patients in regard to their sexual relations, and suggest to them to be moderate in all things, and not to give way to their appetites all the time.

Hugh N. Leavell, (Closing): Dr. Wathen, in speaking of digestive disturbances necessitating surgical procedure, went so far as to state that but few disturbances of digestion are functional in character. I believe that we will realize the truth of this more and more as we study metabolism further and further. There is nothing that is attracting the attention of the medical profession to-day more than the chemistry of the digestive juices, and the further they go into this subject the more they find that disturbances of metabolism have for their origin an organic change somewhere in the body.

In regard to Dr. O'Connor's discussion, I will only say that if he will follow all of his cases of indigestion to the operating room, he will find, perhaps, a great deal more pathology than he is aware of at the present time.

I do not think that we should look at cases of

indigestion from the viewpoint of our specialty, as suggested by Dr. Zimmerman. It is not necessary to examine the rectum of every patient that comes to us for a pathological condition of the stomach.

A great deal has been said about reflex disturbances, but does not the use of that term imply a pathological condition existing somewhere which gives rise to these reflex disturbances, the removal of which cures the trouble? It seems to me that this bears out what I said in the beginning; that drugs have little or no influence upon these conditions. The more we delve into the subject the more we find that these digestive disturbances are reflex in character, secondary to some pathological condition upon which drugs can have no influence.

Dr. Jenkins says that he has seen cases of this kind, superinduced by gallbladder disease or appendicitis, markedly relieved by operation, only to lapse into their former condition within a comparatively short time. Did he, in these cases, look again for pathology about the gallbladder which had been opened? Did he ascertain whether or not there was a constriction of the gall duct, induced by the operation? Did he take into account adhesions which might have formed? In other words, did he look at it from a surgical standpoint, or did he consider the medical condition paramount? If he had looked into some of these cases perhaps he would have found a constriction of the gall duct, a condition more serious than the gallstones, for the removal of which the former operation had been done. Does that prove that surgery was not effective? Does it demonstrate that all of the pathology was eradicated because the gallstones were removed?

In regard to Dr. Askenstedt's remarks, I will say that we all recognize the masterful manner in which the doctor practices medicine; we all know that he is a competent diagnostician; we recognize that, although a little short on the therapeutic end of it, it is possibly better for the patient. And does not that further demonstrate the inefficiency of drugs so far as a cure of these conditions is concerned?

Dr. Askenstedt also mentioned motor insufficiency, and the possibility of relieving hyperchlorhydria by a proper diet, etc. We know, of course, that hyperchlorhydria is easily relieved by proper diet, and drugs, but does this demonstrate that the underlying pathology is not sufficient to demand surgical interference? Some time ago I exhibited to this society a case of perforated gastric ulcer. This man had been under my care for several months, refusing surgical interference. He obtained marked relief from the use of bismuth, purgation, regulation of diet, etc., but in an instant that man's life came within an ace of being snuffed out by the perforation of a gastric ulcer, necessitating immediate surgical interference. Since the operation this man has

not had a symptom of gastric disturbance. This is an instance in which drugs relieved and palliated the condition, but did not cure it.

This proposition is not a proper subject for controversy between the surgeon and the internist. I treat a good many of these cases by internal medication, but does that mean that the issue must be clearly drawn, and that we shall be continually at logger-heads about these conditions in the digestive tract. Of course, there is a time when proper regulation of the patient's diet will have a marked influence upon digestive disturbance, but that does not demonstrate that they will be of any permanent benefit after a pathological condition has developed in the stomach, or the secretions of that organ. I do not say that drugs are not palliative, but so far as a cure is concerned, I still maintain that medicines have no place in the treatment of pathological secretions or pathological lesions.

ARTERIOSCLEROSIS.

By J. M. MORRIS, Louisville.

It is interesting to know that, in ancient times, the arteries were thought to contain air and to convey it to different parts of the body, and from this erroneous idea was derived the name, arteries; the term being derived from two Greek words, meaning "air" and "to convey." The minute structures of the arteries is well adapted to the varying functions which they perform. In every large and medium size artery, three distinct layers, or coats, may be distinguished under the microscope. The inner coat, or tunica intima, is composed of endothelial cells and fibrous elastic tissue; a middle coat, or tunica media, composed mostly of muscular fibres; an external coat, or tunica adventitia, made up of white fibrous tissue. I mention the minute structures of the arteries because upon changes in these different structures, depend the nature and cause of the disease under consideration. The arteries are subject to a number of diseases which may be due to infectious micro-organisms, degeneration with increase of connective tissue, aneurysm, etc. Of the acute infectious diseases, tuberculosis and syphilis, especially the latter, are the most important. Syphilis is one of the most important of all causes of arterial degeneration. Recent bacteriological studies have shown that bacterial infection of the arterial wall is a fundamental and important process. It is often the cause of an arterial thrombosis, and frequently develops into a true arteriosclerosis. Under this general head, arteriosclerosis, is classed a diffuse or circumscribed thickening of the arterial walls, especially of the tunica intima, secondary to inflammatory or degenerative changes in the tunica media. Arteriosclerosis is sometimes found in the young, but is usu-

ally a disease of later life. The disease may be circumscribed or diffused; it may show irregular plaques of a transparent or gelatinous character, which at a later period become hard and fibrous, or even calcified with the formation of brittle, or "pipe-stem" arteries. Sometimes the arteries undergo a fatty degeneration. There is a proliferation of the connective tissue, and a degeneration of the elastic tissue. The arteries thus become less responsive to control, and so interfere with the nervous impulses. In the diffuse form, the proliferation and degeneration are more uniform. Arteriosclerosis is one of the most important of all the diseases, since, by its interference with the proper supply to an organ, it is almost certain to occasion disease of that organ. In pronounced general arteriosclerosis, all the organs of the body suffer. Arteriosclerosis is also one of the most important elements in the production of cerebral hemorrhage. The modern view of arteriosclerosis as a general disease, dates from the papers of Gull and Sutton, in 1872, who called the process "arterio-capillary fibrosis." While in this discussion they dealt particularly with the relation of contracted kidney to arterial changes, nevertheless, in their first two conclusions they clearly announced a conception of arteriosclerosis which has undergone no special change since that time; namely, that there is a diseased state, characterized by hyaline fibroid formation in the arteries and capillaries; and, second, that this morbid change is attended with atrophy of the adjacent tissues. Sutton had an extraordinarily clear idea of the whole process, and of the relation of visceral lesions to the vascular condition.

Thomas, about this time, in his remarkable studies, widened our conception of the pathology of this process. Four great factors may be considered in summing up the causation of arteriosclerosis; namely, the normal wear and tear of life, the acute infections, the intoxications, and those combinations of circumstances which keep the blood pressure above normal.

Let us consider, briefly, each of these factors.

First, as to the wear and tear of life. Of all the organs of the body, the blood vessels alone enjoy no rest. Not only does the blood journey continuously through them at an average rate of ten inches per second, but the walls of the large arteries are subjected to a distending force of two and one-half pounds per square inch, sixty to eighty times per minute; or, 80,000 to 100,000 times each twenty-four hours. The stability of tubing of any sort depends upon the structure and upon the sort of material used, and so it is with the human tubing. With a poor variety of elas-

tic and muscular fibres in the blood vessels, some are unable to resist the wear and tear of every-day life, and at forty years of age have arteries as old as others at the age of sixty. The arteries in the two individuals may look alike macroscopically and microscopically, but they differ in the material used, as it were and the capacity to resist the ordinary strain of life is unequal. The conditions attending modern life are very productive of arteriosclerosis, for a man runs his body machinery at high pressure and often takes less care of it than he does of his motor. The best express engine which the skilled and scientific workman can produce cannot last one-tenth the time, nor do nearly so reliable service when run day by day at maximum speed, as it can when run at a more moderate rate. And so it is in this, our present day of hurry and worry; the human engine must be run at top speed or not run at all, and we cannot wonder that very early signs of hard usage begin to show. In the fourth or fifth decade, even with the best of habits as to eating, drinking, and other modes of life, the incessant strain and anxiety of public life, or of business, may lead to degeneration of the blood vessels. Mental exertion in itself is not injurious, and the life of the student need not be one of great tension, but the mental exertion of the modern business man is of a very different character. Competition is so keen, and environments so stimulating, that even without professional or social ambition, high pressure and arterial tension are unavoidable. The tragedies of life are largely arterial. Nemesis, who was represented in the old mythology as the winged Goddess of the inevitable, may still be pictured with an unbroken wheel—the Wheel of Life—to the ceaseless revolution of which the circulation ministers. And how often does her fatal touch call away, in the prime of life, the best and the bravest men, whose only fault was their unselfish abuse of the body machinery. After the age of forty it is exceptional to examine the arteries without finding some evidence of degeneration, with here and there a small plaque of atheroma, an occasional streak of intimal fatty degeneration, and with this the mitral and aortic cusp losing just a little of their delicate tenuity. With advancing age the arteries become thicker and the atheromatous changes more marked. As a rule, in the very aged, not only are the smaller arteries thickened, but the aorta and its main branches show extensive changes, with calcification. Very exceptionally, however, an old person may be found with singularly healthy arteries. Owing to the more quiet life of the average woman, the disease is oftener found in men than women. Also, it is true that women, as a rule, live longer than

men; hence we have so many widows. Arteriosclerosis may occur in infants and young children, either as occasional patches, or flakes, or even calcified patches in the vessels of the newborn; or, in infants dying of acute infections, streaks of fatty degeneration of the intima and foci or necrosis of the media, are not uncommon. Widespread arteriosclerosis of the smaller vessels may occur without nephritis, and without recognizable cause; or, in congenital syphilis, diffuse or localized sclerosis of the arteries may occur, sometimes very early, sometimes very late. Tremont Smith has lately collected 144 cases of these diseases, in the very young, from the literature on this subject.

As to the acute infections causing arteriosclerosis, I should say that syphilis stands at the head of the list.

Some changes are best described as acute productive arteritis, others as degenerative changes, which come in the category of chronic arteritis. Extensive arterial changes in children and infants are very often syphilitic. We have also learned to recognize the great frequency of scarlet fever, measles, diphtheria, small-pox and influenza as primary causes of arterial degeneration. It has long been known that in typhoid fever, areas of necrosis and fatty degeneration and necrosis of the arteries are met with. The observations of Thayer show how important are the cardio-vascular relations of this disease. Of 32 post-mortems, made at the Johns Hopkins Hospital, evidence of sclerosis in 30 were noted, and in 21 of these cases the changes were recent. Thayer also examined 190 patients who had had typhoid fever within the last fourteen years, and found that 40 per cent. of the patients between the ages of 10 and 50, had palpable radial arteries. At the Franz Joseph, Wissal examined 300 bodies of children dead of acute infections, and in 80 he found evidence of arteriosclerosis, usually in the form of patches in the coats of the larger branches, but the smaller branches were involved also.

Arteriosclerosis is frequently found associated in the same patient with tuberculosis. Especially is this true in cases where the tuberculosis is of more than one or two year's standing. It has been observed by many writers that, in chronic phthisis, the superficial blood vessels in most cases are more or less thickened. Of the poisons which have an important influence on the blood vessels, some are exogenous and some are endogenous. Of the special exogenous poisons, alcohol, lead and tobacco perhaps should be first mentioned the first, alcohol, being very generally regarded as a potent factor in causing degeneration of the blood vessels, although in man it is difficult to separate, in many in-

stances, its effect in producing this disease from other causes. Of late years, there has been a tendency by many to rebel against the popularly accepted theory that alcohol plays so important a part in the production of this disease, and in France, some men (Lancero and others) reject the theory entirely. R. C. Cabot also holds the same opinion. But there can be no reasonable doubt that alcohol plays an important part in the production of this disease, the difficulty being in determining just how far its influence has reached in any given case. For instance, in a middle aged man who has drunk freely, eaten largely, and worked hard for many years, it is impossible to say which of these factors has played the greater part in the production of his hardened blood vessels. Alcohol may act as a direct poison, thus causing necrosis of certain elements of the blood vessels, or it may be a factor in maintaining a constant high pressure.

Tobacco is another poison about which it is difficult to obtain conclusive evidence. It is easy to produce extensive degeneration of the aorta in animals with nicotine, experimentally; but when one considers the extraordinary quantity consumed by a man during many years, and shows no trace of vascular changes above that incident to the ordinary wear and tear of life, it is not easy to understand how it bears the great influence attributed to it in the production of this disease, yet we do know that it rapidly raises the tension, and may cause spasm of the arteries, which factor may account for the cases of sudden death in young and middle-aged men in whom excessive use of tobacco has been the only etiological factor. Angina pectoris is sometimes associated with the use of tobacco, and the influence may be through introducing an arteriosclerosis of the coronary artery. It has been shown that lead has an important effect upon the blood vessels. A slowly-developing sclerosis is common among painters and others who habitually handle lead, by gradually taking small quantities of the lead into their system. The direct toxic action of lead upon the blood vessels, the disturbance of metabolism which leads to gout and chronic interstitial nephritis all of which are associated with high tension, favor sclerosis.

Of the endogenous poisons which may produce arteriosclerosis, may be mentioned all the conditions of perverted metabolism. The thickening of the arteries in gout, in diabetes, in chronic Bright's disease, and obesity, may be due to the action upon the blood vessels of poisons retained in the system.

With reference to the conditions which keep up high blood pressure, we must first remember that the pressure with which the blood circulates within the arteries, varies greatly

within limits, in order that the circulation may adapt itself to the varying conditions of life. Among the causes which tend to produce heightened blood pressure, may be mentioned, first, over-eating. Excess of food and drink acts in two ways; (1) in keeping the blood vessels constantly distended; (2) in the process of primary and secondary metabolism, substances may be found which are directly toxic. This is the condition so well described by Francis Hare as hypopyremia, a state in which the system is damaged by products of imperfect metabolism. It is a well-known fact that many cases of arteriosclerosis are met with in cases who have always been temperate in everything except at the table. It is also true that in the United States, arteriosclerosis is very common among the well-to-do class, who, as a rule, are abstemious so far as alcohol is concerned, but exceedingly careless and indulgent in the matter of eating. The fact is fully established that one main cause of arterial pressure in middle life is excess of feeding, that is to say of food in excess of the work and exertion. The railroad engine capable of running fifty or sixty miles an hour when stoked for that purpose, if put in the station yard to shunt empties, will soon go to pieces. This is what many of us do with the body engine. We supply the fuel sufficient to run fifty miles an hour when, in fact, we fail to run it more than eight or ten miles an hour. In our bodies, as in the engine, damage is certain to follow from the accumulation of waste and the disproportion between intake, work done, and output.

To bear out the statement made by some observers that meat-eaters are more prone to arteriosclerosis than others we have this fact; that, among the Indians and Japanese, who subsist largely on a vegetable diet, this disease is less prevalent than among others. In no way is blood pressure more surely heightened than by very severe muscular efforts prolonged over a great period of time. Here we have damage done to the cardio-vascular system, which produces hypertrophy of the heart, as is often seen in miners, and athletes.

Etiologically, then, there are three great causes of arteriosclerosis; the involuntary, in which the degeneration is caused by the ordinary wear and tear of life, and which is as natural as grey hair and failing eyesight; the toxic group, in which the degenerations are caused directly by the poisons of acute and chronic infections and intoxications; and the hyperperiptic, in which the degeneration follows persistent high arterial tension. In a man of 50 or 60, all of these conditions are usually present in greater or less degree. It is rare to find the arteries entirely free from

disease at any age, even in infants, while in the bodies of middle-aged persons some disease of the arteries is always present, and as a rule, the older the patient the more pronounced the condition becomes.

In arteriosclerosis the process of the disease may be much more advanced in some arteries than in others. For instance, the arteries of the brain may be stiff and hard while the arteries of other parts of the body may be much less affected; or, the coronary arteries may show extensive changes in the young while all other blood vessels may appear healthy. Recent research leads to the conclusion that in the ordinary type of arteriosclerosis, the primary lesion is in the media, either productive or degenerative.

Function is disturbed by arteriosclerosis in three ways. Lessened activity of an organ follows the disease in its progressive form, and there is lessened capacity for material work by that organ. The changes which come with old age are largely vascular. With a reduced blood supply the organ becomes less and less active, atrophy slowly but progressively comes on, and in turn may become firmer and harder. In old age every organ and tissue shows changes which may be attributed to arteriosclerosis. When the disease reaches the final and obliterative stage, if in an end vessel, necrosis follows in the territory supplied. Or, as so often happens, if it is in the peripheral vessels of the foot or hand, gangrene supervenes. Again, the disease renders the small arteries more prone to spasm than normal vessels. We have an example of this in the leg, the spasm being accompanied by pain and loss of function. The diminished volume of the pulse is readily perceptible. The foot becomes pale, with considerable pain, and muscular disability.

As has already been intimated in this paper, a patient may have no well-marked symptoms of this disease, and the condition may be met with in a casual examination, as for life insurance. It is a common experience with the trained clinician to find this disease in persons who look well and who are able to perform the duties of every-day life. Sudden death may be the first and only manifestation of the disease. Rupture of a blood vessel in the brain, thrombosis of one of the coronary arteries, rupture of a small aneurysm, acute dilatation of the heart—any one of these may carry off a man in whom there has never been any suspicion of an organic lesion. Natural death comes through the blood vessels. The description in Ecclesiastes of the gradual failure of the vital powers in man is an epitome of the clinical feature of senile arteriosclerosis. In a man who has led a very energetic life, has worked hard with his muscles, eaten much, drank rather freely, the palpable

arteries are thickened, the blood pressure heightened, an increase in the vigor of the cardiac impulse, the apex beat is a little dislocated outward, the first sound is thudding and prolonged, while the second is accentuated; such a patient may look to be a very robust man, and yet on careful examination we find the exact contrary. When these conditions are present under the fortieth year, they must always be looked upon as serious, although not necessarily fatal in the immediate future. Many of these patients at this age come to us suffering with neurasthenia, irritability, sleeplessness and emotional, probably the first time they have ever consulted a physician. The patient may present quite early in the disease, all the complex and varied manifestations of a nervous breakdown. In the more advanced stages, the cerebro-spinal features are among the most important and interesting. Headache is an early and distressing symptom, associated as a rule with high pressure, and often relieved temporarily by measures which reduce the high pressure. And just here, I would like to say that many cases of arteriosclerosis are overlooked, and these head symptoms assigned to some other cause.

Vertigo is another very common symptom and may become very distinguishing, although usually temporary and never of the severity of that associated with Menier's disease. One of the extraordinary cerebro-spinal manifestations of the disease is the occurrence of attacks of transitory disturbance of function of parts of the brain or cord, leading to hemiplegia, monoplegia, aphasia, or even paraplegia. Osler makes mention of a case in his last work which I think is worth repeating here. A man about forty years of age awoke one morning to find himself unable to speak, or to use his right hand. This condition had been preceded by one attack of slight palpitation of the heart and shortness of breath. The paralysis passed away in twenty-four hours and he recovered his speech almost as quickly. He had more than a dozen of these attacks, some lasting a little longer than others, but with complete recovery from each attack, and this was the first time the patient was known to have arteriosclerosis. I am inclined to the belief that cases of this kind are not rare, especially where the disease predominates in the cerebral vessels. The attacks are sudden and recovery is complete in most of this class of cases. We should remember that their transitory nature with complete recovery and the extraordinary frequency of the attacks, puts cerebral hemorrhage, embolism and thrombosis out of the question, and therefore, the condition must be an angiospasm similar to that which produces manifestations of Raynaud's disease. Convulsions of an epi-

leptiform character may occur and, in the absence of syphilis and lead poisoning, convulsions occurring in middle aged persons should always excite suspicion of arterial hardening. There are three important groups of causes in which the dominant symptoms of arteriosclerosis arise from affections of the heart; the valvular, myocardial and coronary. In a considerable number of aortic and mitral valve lesions, the insufficiency is due to a process in the segments identical with that which goes on in the vessels. In general arteriosclerosis gradual failure of the hypertrophied cardiac muscle is a common and serious event, leading to the characteristic picture of dilatation and systole. In the case of the coronary arteries, the main branches, the orifices, or the smaller vessels may be affected.

Referring to the renal condition in this disease, there are two groups to be considered; that associated with the small contracted kidney, following acute nephritis, or coming on insidiously in gout or chronic lead poisoning, in which there is an extreme grade of arterial hardening which must be regarded as secondary; and the true arteriosclerotic kidney, which is the red, beefy organ, firm, hard and dark in color, somewhat enlarged in most cases. From the general appearance of the man not much can be learned of his actual condition. A robust, vigorous man in the prime of life may have vessels in the most advanced stages of this disease. The active muscular business man of 45 or 50 years who never in his life had to spare himself and who has prided himself on his fitness for any and every thing, is shocked to find suddenly there is something wrong with his machinery; and to the young-old man who has reached the grand climacteric period without a day's illness, Nemesis whispers "time is up."

The cardinal points in a case of arteriosclerosis are usually well marked. Thickness of the peripheral vessels, signs of an hypertrophy of the left ventricle shown by the apex beat being dislocated outwardly, heightened blood pressure, slight and variable albumin in the urine. As a rule this quartet of symptoms is present in a large number of cases when they first come under observation of the physician, and at this stage let me say, the damage has already been done and is beyond repair. The important part, therefore, for the physician to learn is to be able to recognize the disease in its early stages when there is some chance that its progress may be checked. By palpation we are able to judge with fair accuracy the degrees of the thickening of the vessel wall, but it requires not only experience, but education of touch to form an accurate judgment of the state of the arteries. A perfectly healthy vessel when contracted may feel cord like. On the other hand, in a

radial artery definitely thickened, but in a state of extreme relaxation, the hardening of the artery may escape detection. The introduction, in late years, of clinical instruments for measuring blood pressure, has given one important method of estimating accurately the condition of the arteriosclerotic patient early in the disease or before the thickening of the vessel is evident. The blood pressure may be persistently high. The pre-sclerotic stage, as it is called, is important to recognize and yet it is not always true that we are able to trace all the stages in a given condition.

As for treatment I shall be brief. Once degeneration, fibrosis, and calcification have taken place, medical measures cannot restore the normal structures of the arteries; but this does not mean that the condition is always absolutely hopeless, for much may be done to prevent the sclerotic condition from increasing and much may be done to relieve symptoms. The treatment may be carried out along the following lines. First, I should say in general, the patient should be urged to live as peaceful a life as possible, cutting off all sources of mental strain and worry. A protracted holiday, as it were, may be most helpful. But it is not wise, as a rule, to urge a man to give up business entirely, especially the man who has led an active business life, for too often this is followed by neurasthenic breakdown, but the most important, as well as the most difficult, part of the treatment is to so arrange a man's life that he may have moderation in everything pertaining to his every day life. So long as the patient's duties can be lightened there is no reason why he should not continue. As a matter of fact when there are signs of cardiac failure, or if the mental changes are plainly marked, it would be wise to urge complete rest. Such patients require the conscientious advice of friends and physician, for many men on hearing from a physician that they have disease of the arteries are inclined to become despondent and give up hope, when under proper advice, they may have a good many years of usefulness before them. Arteriosclerosis, when recognized early in a man forty or fifty years of age, may not shorten his expectancy more than five or six years; provided, however, he is given good advice by his medical adviser and is entirely willing to live the remainder of his life according to that advice. Proper exercise is of importance in the management of this disease. Golf, horseback riding, walking, bicycling, all in moderation, are advantageous. Relaxation of the vessels of the skin and of the parietal arteries generally, which follows moderate exercise, lowers the blood tension and relieves the heart, while all sudden efforts likely to throw a strain on these vessels should be

avoided. The action of the skin should be promoted by a daily bath. The one great and essential factor in the diet of arteriosclerotic patients is a reduction in the amount of food taken. He should be taught to gradually reduce his food supply until he finds the minimum amount with which he can maintain mental and bodily vigor, and he will often be surprised that one-third or even less than the amount he has been accustomed to consume is sufficient. He may take a cup of tea and a boiled egg, a couple of slices of toast for breakfast; a vegetable soup with a rice pudding for luncheon; a piece of fish, a couple of vegetables, stewed fruit, with a glass of milk, for dinner. With a diet along these lines an arteriosclerotic may hopefully pray the prayer of Hezekiah of old, and get, like him, a fifteen year extension. He can do without meat perfectly well. Oysters, eggs in moderation, and fish may be taken with plenty of fruit, vegetables, bread and butter with plenty of milk, these articles all being especially easy of digestion. Buttermilk and sour milk are a favorite diet with many of these cases and are found to act remarkably well; and, in this connection, it is interesting to note the strong opposition of Metchnikoff as to the value of the lactic acid products in preventing abnormal processes of fermentation in the large intestine. Spirits of all kinds should be taken in moderation and a man who has been a hard smoker should reduce his allowance to two or three cigars a day.

Of remedies believed to have a direct influence upon the coats of vessels, iodide of potassium alone is of special value. It is stated, and probably correctly, that arteriosclerosis can be prevented, experimentally, if, coincidentally with adrenalin, iodide of potassium is given to the animal. In all syphilitic cases it should be given very freely and even in other cases the drug should be given in moderate doses, fifteen to twenty grains three times daily and kept up for several months. It is believed that iodide of potassium lessens viscosity of the blood and in that way lessens the work of the heart. The blood pressure is much more efficiently lowered by proper diet than by drugs.

Of the drugs which have an important influence the nitrites are the most useful. The commonly used nitroglycerine is often effective, but usually is given in too small doses. Sodium nitrite, in one to four grain doses every three or four hours, has a more permanent action and is often of greater value. Arsenic in small doses is helpful, especially in cases of anaemia. In the crises of hypertension, brisk saline catharsis is most helpful. In all cases it is well to bear in mind that the only valuable measures for permanent reduction of blood pressure are the hygienic

and dietetic, and as Hippocrates taught more than 2,300 years ago, the most we can do is to assist nature in preventing the patient from becoming worse.

DISCUSSION.

Milton Board: I have some well defined ideas as to the management of certain cases of arteriosclerosis. We must bear in mind that we have to deal with a condition of the peripheral vessels as the result of an hypertrophy of the left heart, and I do not believe that we have any therapeutic agents of any particular value, unless it be iodide of potassium in selected cases. I do believe that absolute rest is imperative, and it is remarkable what the actual rest cure will do for a great many cases of the worst form of this condition that we are called upon to treat. The patient should be placed in bed and kept there for a month, or two months. This gives the heart less work to do, the patient does not consume much food, and assimilates what he does take. The results from this treatment in many cases is surprising. Of course, this treatment can be carried out in an institution to greater advantage than in a private home, because many times these patients will not take sufficient rest. Drugs that stimulate the heart do harm, and in this connection I wish to condemn all forms of electrical treatment. I have never seen a patient treated by galvanism or faradism, or any of the newer forms of electricity, that was not made worse.

Gaylord C. Hall: I wish to thank Dr. Morris for the splendid paper he has given us. One point that I wish to call attention to is the value of the ophthalmoscope in the diagnosis of arteriosclerotic changes, especially in the brain. I had a case in a woman, 62 years of age, who had pronounced cerebral symptoms, accompanied by vertigo, and on several occasions she had lapsed into unconsciousness, remaining in that condition for half an hour in one instance. Practically all of her cerebral functions were in abeyance. She was sent to me to determine whether or not these symptoms indicated a needed change in her glasses. After going over her refraction and finding no change necessary, I made an ophthalmoscopic examination of the fundus and found the characteristic evidence of arteriosclerosis. In this case, the increased tortuosity of the retinal veins had not advanced sufficiently to give them a beaded appearance, which is another characteristic feature of these cases. More than that, the arteries themselves show a light-streak on either side, are somewhat contracted, and where they cross the veins the circulation of the latter is cut off. These conditions are absolutely characteristic of arteriosclerotic changes. Later, we may have rupture of these hardened arteries and hemorrhage. While these symptoms are not absolutely pathognomonic of general arteriosclerosis, still if we find the terminal vessels of

the retina so diseased, it is pretty strong presumptive evidence that the same condition exists in the cerebral vessels, although it does not follow that this is true of the peripheral vessels all over the body.

S. G. Dabney: I wish to indorse what Dr. Hall has said in regard to the value of the ophthalmoscope in the diagnosis of arteriosclerosis. The books usually divide the eye symptoms into three stages. In the first stage we have increase in the light streaks alongside the arteries, and interruption of the continuity of the veins where they are crossed by the arteries; in the second stage, the increased tortuosity and beaded condition of the blood-vessels, and, in the third stage, hemorrhage of the retina. These stages indicate different degrees of arterial change in the retina. One or two other conditions are also found at times, one of the most interesting of which is thrombosis of the veins. This used to be considered as embolism, but it is now generally conceded that it is a thrombotic condition. Retinal spasm also occurs at times, and it has fallen to the lot of several men in this country to have had an opportunity of examining the retina, during a spasm. It is said to show a contracted condition of the blood vessels, corresponding with the diminution in the patient's sight. This spasmodic condition of the retina very often precedes thrombosis of the retinal vessels, and both of these conditions are apt to be the result of arterial changes.

Another evidence of arteriosclerosis which is often seen by the eye and ear men, is nose-bleed, which is a very important symptom. I have seen a number of cases of nose-bleed in persons past fifty years of age, in whom it was the first indication of a condition of arteriosclerosis. I never see a case of nose-bleed in a person past middle age that I do not have the urine analyzed and the blood pressure taken. In this condition it plays a double role, being partly a symptom and partly a remedy, because it tends to relieve a more serious condition.

We also frequently see tinnitus aurium as a manifestation of arteriosclerosis. Occasionally though not often, there may be some difficulty in distinguishing between vertigo due to labyrinthine disease and that caused by arteriosclerosis.

Andrew Sargeant: I wish to thank Dr. Morris for the excellent paper he has given us.

The problem of life is one of nutrition and elimination, and it is frequently a very difficult matter to tell which of these is at fault. It is also a difficult matter to tell whether the increased blood pressure in arteriosclerosis is a disease *per se*, or whether it is a protective process of which Nature undertakes to protect diseased organs from the excessive pressure of the circulation, or from infective material in the blood by furnishing it in diminished quantity.

I am sorry that the essayist did not mention

the sphygmomanometer. I have had some experience with it and in the further discussion I wish some one would be kind enough to tell us of their experience with the sphygmomanometer in this condition.

Ben Carlos Frazier: It has been my fortune to have seen quite a number of these cases recently. I think everything that has been said in regard to the value of drugs in this condition is true. I do believe, however, that the bromides, in conjunction with the iodides, are of benefit in some cases, especially elderly people in whom there is a certain amount of irritability present, and who are unable to sleep because of nightmare, restlessness, etc. Such cases are considerably benefited by the bromides.

Fritz O. Askenstedt: I have listened to see how many points Dr. Morris would cover in his paper, as the subject is a very big one.

In a disease that is incurable and progressive, the proper treatment is to remove the cause, and especially in arteriosclerosis we should ferret out the cause, as far as possible, and remove it. We know that blacksmiths are prone to develop arteriosclerosis in the arms; letter-carriers have a tendency to arteriosclerosis of the lower extremities; brain-workers of the brain; those who indulge in excesses in eating and drinking develop arteriosclerosis of the splanchnic arteries, and we know that even in mitral regurgitation or mitral stenosis, the high pressure in the pulmonary arteries is the result of arteriosclerosis there. So, there is no doubt that over-functioning of itself becomes a cause of arteriosclerosis. We quite frequently find that a local arteriosclerosis has very little effect upon the general circulation; that the heart is normal in size and the arterial pressure nearly normal, with the possible exception of arteriosclerosis of the brain, where the vasomotor center of the medulla does not receive a sufficient blood supply, which, of course, causes a higher arterial tension.

The increased blood pressure and hypertrophy of the heart that we find in general arteriosclerosis, indicates a general toxemia, such as alcoholism, errors in diet, auto-toxic conditions, etc. We should determine, from the symptoms, what causes the condition, whether local or general, and endeavor to remove the cause, and when we have done this we have carried out the most important part of the treatment of these cases.

O. H. Harris: The paper was a very scientific one and beautifully written. I believe that, if we could eliminate arteriosclerosis from the ills to which the human race is heir, half of the doctors would have to go out of business.

We hear so much about syphilis in connection with arteriosclerosis; nearly every man who has anything to say about arteriosclerosis mentions syphilis. If it is true that syphilis is the principal cause of arteriosclerosis, then the majority of the human family must have the latter disease.

Some syphilographers claim that, in the course of time, the entire human race will be immunized against syphilis by virtue of the disease being transmitted. I believe that, in the main, it is an hereditary condition. Nearly all the deaths that have occurred in my family have been due to arteriosclerosis. It has been said that a man is as old as his blood vessels, and I believe that there may be an hereditary tendency toward degeneration of the blood vessels. It depends largely upon what sort of material the individual is made of in the beginning. As a matter of course, over-eating, alcoholism, excessive use of tobacco, etc., with poor material as a basis, would be apt to bring about more pronounced changes.

I agree with Dr. Morris that the tragedies of life are largely due to arteriosclerosis. What could be more tragic than the case of the man who has hemorrhage into the internal capsule and drags one leg all the rest of his life? What could be more tragic than the people who fill up our insane asylums? I believe that a great many cases of insanity are due to arteriosclerosis of the brain. I am at present attending a physician who is suffering from arteriosclerosis, with a blood pressure of 160. That man is insane at the present time—temporarily, I believe. Just as soon as the blood pressure is reduced he gets better.

We all eat too much. I think the human body is comparable to the action of an ordinary stove. We put fuel into the stove to produce heat and energy, and as a result of the combustion certain by-products are formed—ashes, which goes into the ash-box, and smoke which goes up the chimney. This is analogous to the action of the human body; we put in food to produce heat and energy and the by-products are thrown off by the enunctories—the bowels, kidneys and skin. When we eat too much the enunctories become clogged, and as the result on the part of Nature to eliminate the excrement, the blood pressure is raised, which finally results in changes in the blood vessels themselves.

In my opinion, nitrite is of considerable value in this condition. I speak of nitrite, not nitrate, or soda. It should not be given in one or two grain doses, but in doses of five to ten grains, three times a day, at the same time cutting down the amount of food taken. Also, prolonged baths, of an hour or more, in hot water, will reduce the blood pressure, especially in the aged. I believe, too, that the bromides have a very favorable influence upon patients who are suffering from emotionalism, and disturbed circulation in the brain, brought about by arteriosclerosis.

This is a big subject and it does us good to think about it.

Hugh N. Leavell: It is an interesting subject that Dr. Morris has brought before us to-night.

* If we take into account the five factors that have to do with the regulation of the circulation of the blood, we will recognize that at least

two of these are materially interfered with by arteriosclerosis. We can readily understand how we may have myocarditis as a common change; furthermore, the hardening of the blood vessels interferes with the peripheral circulation. Therefore, we have obviated at least two of the factors that go to make up the normal circulatory apparatus, and, this being true, it would appear that when arteriosclerosis begins we might as well throw up our hands and give up the fight. As a matter of fact, it is not quite so serious at that, but we do recognize that it is an ineradicable condition after it has gotten a good hold upon the mechanism.

I disagree with some of the therapy that Dr. Morris has suggested; namely, the use of adrenalin chloride associated with iodide of potassium. It may be that adrenalin chloride, contracting the blood vessels and subsequently dilating them, brings about greater resiliency of the vessel walls, but I would hesitate to use it in persons past middle age with marked arteriosclerotic changes. I believe the constant use of the iodides is better than any other drug, but it should be given in small doses, an hour after meals, and long continued.

After all, the keynote of the subject was sounded by Dr. Askenstedt when he said that we must ascertain the cause and remove it. We recognize that over-eating, over-indulgences, loss of sleep, etc., are perhaps more important causative factors than anything else. When we take into account the fact that, once the blood vessels have hardened and undergone fibrosis, involving the muscular coat, which of necessity is the resilient part of the artery, we can readily understand that we are up against a hard proposition so far as a cure is concerned.

J. M. Morris, (Closing): I wish to thank the gentlemen for their kind discussion of this paper.

In regard to Dr. Leavell's remarks, I will say that I did not mention adrenalin chloride in connection with the treatment of arteriosclerosis; I simply stated that it had been used, experimentally, to produce this condition.

THE USE OF VACCINES IN THE TREATMENT OF GENITO-URINARY CONDITIONS.*

By HERBERT BRONNER, Louisville.

We believe that vaccine therapy is here to stay. Although vaccines, or, more properly, bacterins, have been in use several years now, work along this line is still in its infancy. With greater skill in the technique of the preparation of the vaccines, with greater accuracy in the determination of the exact causative organism, with a better knowledge of

the indications for the use of the vaccines—which, of course, can only be acquired by the study of many cases, and lastly, with a clearer idea of dosage and interval, the usefulness of this form of therapy will be wonderfully enhanced.

It must be remembered in the beginning, that vaccine therapy is not a "cure-all." Its most sanguine supporters have never claimed it to be such. Those men have gotten the best results who regard the vaccine as a most useful adjunct in the treatment of disease.

The deleterious effects of bacteria on the body may be exerted in one of two ways. Some organisms produce the poisonous substance from the media on which they grow; in other words, the blood serum. These toxins, or exotoxins, are soluble, easily diffused throughout the body, and are responsible for the symptoms present in the disease. The *Klebs-Loeffler bacillus* is the type of organism which produces an exotoxin.

A far larger class of organisms produce the poisonous substance without themselves, and these substances are called endotoxins. The endotoxins are not diffused in the blood stream, and are only freed by the death and disintegration of the bacteria. The *staphylococcus* and *streptococcus* are types of this class of bacteria.

In the diseases due to the first class of bacteria, the chief danger to the infected individual is from the toxins. In such cases an antitoxin neutralizes the poison and, therefore, produces passive immunity. In diphtheria, for example, where the bacteria produces 90 per cent. soluble toxin, and only 10 per cent. endotoxin, an antitoxic serum is the ideal therapeutic agent.

There are, however, only a few conditions where antitoxic sera are available. The majority of bacteria produce the baneful substance within themselves, and in these cases antitoxic sera are of little or no aid. For example, the *streptococcus* produces about 90 per cent. endotoxin and 10 per cent. exotoxin. In such infections it can be readily seen that an antitoxic serum would have little value.

To combat the endotoxins, we must overcome the bacteria themselves; in other words, we must resort to active immunity in contradistinction to the passive immunity acquired in such diseases as diphtheria. Nature's defensive forces against the last class of diseases are unquestionably varied, but it is believed, by a large class of observers, that phagocytosis plays a most important part in overcoming these infections.

Sir Almroth Wright is one of those who believe that phagocytosis is one of Nature's greatest agents in combating infection. After a most exhaustive study of this subject, he reached the conclusion that there are cer-

*Read before the Muldraugh Hill Medical Society, Elizabethtown, Dec. 14, 1911.

tain substances in the blood which prepare the bacteria and render them susceptible to the action of the leucocytes. "Without such preparation the leucocytes are unable to ingest bacteria, and this defensive power of the organism is in abeyance." These substances in the blood serum, which as so essential to phagocytosis, Wright calls opsonins. He found that the opsonins varied within wide limits, especially in disease, and coined the phrase "opsonic index" to express this. Synnott defines opsonic indexes, "the expression of the measure of the phagocytic power produced in a sample of washed leucocytes by the serum of the individual in question, as compared with the phagocytic power in a similar sample of leucocytes by the serum of one or more healthy individuals." The index is expressed as a fraction of units. If one says that a patient has an opsonic index of .5, to the colon bacillus, it means that he has but half the number of opsonins necessary to combat the infection.

Wright went one step further, and discovered that the injection of sterile suspension of dead bacteria, corresponding to the infecting agent, caused an increase in the number of opsonins, thus increased phagocytosis, and in this way strengthened one of Nature's chief defensive agents against a large class of infections.

This class of therapy is called vaccine, or inoculation therapy, and confers active immunity upon the patient in contrast to the passive immunity conferred by the anti-toxic sera.

As stated before, vaccine therapy is not to be regarded as a panacea. It is essential that the proper disease be selected for vaccine therapy. The more localized the infection, the more decided the results which will be obtained. In those conditions where the bacteria are in the blood stream and systemic symptoms are marked, as in septic endocarditis, vaccines, if used at all, should be given in very small doses, and controlled most carefully by the opsonic index.

In this paper we will consider only those infections of the genito-urinary tract due to bacteria other than the gonococcus and the tubercle bacillus, in order not to make its scope too great. These infections will include those due chiefly to the colon group, the staphylococcus, and streptococcus. We have now used vaccine therapy sufficiently long to have come to the conclusion that, in many suppurative conditions of the genito-urinary tract due to these organisms, where there is not a definite abscess formation, or where there is not some obstructive intervention, either sure or marked amelioration may be expected from vaccine therapy.

The first essential in the use of vaccine ther-

apy is accuracy in diagnosis. We have endeavored most carefully to determine, in each case, the nature of the invading organism. Our observation in this respect corresponds closely to that of others—the enormous preponderance of the colon bacillus in these infections, especially in the upper part of the urinary tract.

In the cases of pyelitis, the colon bacillus was almost invariably present. In these cases occurring in the female, the infection may have been ascending in character, the shortness of the urethra and the proximity of the external genitals accounting for this type of infection. Those cases occurring in the male, however, can hardly be accounted for in this way, and must have been either haematogenous in character, or by contiguity from the intestine, etc.

In the cases of chronic prostatitis of long standing, the colon bacillus was also found at times, frequently accompanied by the staphylococcus.

In the mixed infections of tuberculosis of the bladder, kidney and prostate, the colon bacillus was found almost invariably, and was a greater factor in the causation of fever, as results showed.

In several cases of cystitis, post-operative in character, the colon bacillus was found in pure culture. This was especially so in several cases in the female where the retention catheter was used, following the operation of perineorrhaphy. These cases all respond to the use of the colon vaccine.

One case of chronic cystitis, in the female, was only partially relieved by an operation for retroversion. An examination in this case revealed a pure culture of colon bacillus. Here again the *modus operandi* was plain. The retroversion caused a chronic congestion of the bladder, and this congested mucous membrane formed a splendid culture ground for the ubiquitous colon bacillus.

The staphylococcus was found in several cases of pyelitis but never alone.

In the cases of chronic prostatitis, especially of long standing, it was found to be the most prevalent organism. The work of the late De Santos Saxe Notthaft, and others, have absolutely shown that, the older the prostatitis, the less likelihood of finding the gonococcus and the more likelihood of finding other organisms, especially the staphylococcus. Saxe found the staphylococcus in 74 per cent. of cases of chronic prostatitis. The futility of endeavoring to cure these old cases of prostatitis without making an attempt to overcome this infection is evident.

In the mixed infections of tuberculosis, whether of the bladder, kidney or prostate, the staphylococcus was usually found. In several cases of chronic urethritis the staphy-

lococcus was found to be the prevailing organism.

The streptococcus was found in several cases of pyelitis, usually in combination with the colon alone, or the former two. It was also found in the tuberculous cases.

Having determined just what organisms are responsible for the condition at hand, the next question which arises is as to the type of vaccine which is to be used—whether a polyvalent stock vaccine, or an autogenous vaccine. On purely theoretical grounds, an autogenous vaccine ought always to be used, but there are, unquestionably, cases where the time that is needed to make an autogenous vaccine would be an important factor, and in these cases a good polyvalent vaccine will be found to be very efficacious. In the very acute cases of pyelitis, the several days needed to make a vaccine would cause a rather trying delay in treatment. In these cases we have used the stock vaccine, and our results have been most striking. In none of these cases was it necessary to employ an autogenous vaccine later. Even in the acute colon infections we have seen remarkable results from a good polyvalent stock vaccine, although it is said that, particularly in the infections due to the colon group, an autogenous vaccine is indicated, because of the varied strains of the organism.

In the chronic cases, on the contrary, where time is not a factor, we always employ an autogenous vaccine. In these cases, the organisms are often very numerous, and change from time to time. In the mixed infections of tuberculosis, and in the cases of chronic prostatitis, we always use an autogenous vaccine, having a fresh supply of vaccine made after using six doses of any one supply.

The matter of dosing is a most difficult one for which to formulate any rules, and we believe that each man will have to determine the dose for the case at hand, after careful observation of the clinical phenomena in many cases. Following the dosage by the opsonic index is impracticable for the average practitioner, for the determination of the index requires a high degree of laboratory skill, the consuming of a great deal of time, and a decided expense to the patient.

In streptococcal cases we have usually begun treatment with small doses, while in most colon and staphylococcal cases we have not hesitated to use fairly large doses. Ross' rule is a very good one to remember: "The more severe the case, and the less satisfactory the clinical response, the smaller the dose."

The character of the negative phase is often helpful in determining the dose. If the negative phase is absent or exceedingly short, and is followed by a very short and slight positive phase, the dose has been too small. When the

negative phase is prolonged and the symptoms are decidedly increased, the dose has been too large. When the negative phase is of moderate degree, yet decisive in character, and, as a rule, not longer than 24 hours duration, and is followed by a good positive phase of several days duration, the dose has been correct.

In the second instance—that is, where the symptoms of the negative phase are exaggerated, as evidenced by repeated chills, high fever, great frequency of urination, pain, etc., the interval should first be lengthened and then the dose reduced. In our experience, as before mentioned, the best results are obtained in those infections where there is a decisive negative phase, of about 24 hours duration. The symptoms of this phase may be constitutional or focal. The former may consist of a rise in temperature, even a slight rigor, malaise, aching feeling, and headache. The focal symptoms will, of course, depend upon the lesion. In kidney conditions, there is tenderness over the affected organ, increased frequency of urination, and pain. In prostatic cases there is fullness in the gland, pain at the end of urination, referred pain, etc. We have found that in tuberculous cases especially, great care must be exercised in dosage so as to avoid a prolonged negative phase. We have selected the following cases from our records as illustrating the types of infections in which vaccines were employed.

CASE I.

T. U., age 16. Diagnosis, right-sided acute pyelitis. Patient had a chill on July 31st, 1911, followed by high fever, frequency of urination and excessive pain on voiding. Saw patient in consultation on August 2nd, 1911. Temperature at 8:00 a. m., 101; pulse 100.

Examination revealed decided tenderness over right kidney, with pain radiating down the ureter. Examination of urine showed pus in great abundance, highly acid, 1-2 per cent. albumin. Bacteriological examination of specimen showed colon bacilli, staphylococci and streptococci. Because of the severity of the symptoms, it was decided to use a polyvalent stock vaccine. Vaccine given at 10:30 a. m. At 4:30 p. m., temperature 103.2-5; pulse 110.

August 3rd. 8:00 a. m., temperature 101; pulse 100. 4:00 p. m., temperature 101.1-2; pulse 94. The patient looked very badly.

August 4th. 8:00 a. m., temperature 100; pulse 90. 4:00 p. m., temperature 101; pulse 92.

August 5th. 8:00 a. m., temperature 99; pulse 82. 4:00 p. m., temperature 100; pulse 86.

August 6th. 8:00 a. m., temperature 98.6;

pulse 72. 4:00 p. m., temperature 99.4; pulse 76.

August 7th, 8:00 a. m., temperature 100.5; pulse 80. 4:00 p. m., temperature 101.5; pulse 90.

Urine examined this day showed less pus, colon bacilli, few staphylococci and streptococci. As there had been a slight rise in temperature, we decided to give another dose of vaccine.

August 8th, 8:00 a. m., temperature 101.2; pulse 80. 4:00 p. m., temperature 102.1; pulse 90.

Vaccine was given at 10:30 a. m.

August 9th, 8:00 a. m., temperature 98.1; pulse 72. 4:00 p. m., temperature 99.2; pulse 72.

August 10th, 8:00 a. m., temperature 98.4; pulse 72. 4:00 p. m., temperature 98.6; pulse 72.

August 11th, 8:00 a. m., temperature 98.6; pulse 72.

Examination of urine showed no albumin, much less pus, and no colon bacilli; subjective and objective symptoms all cleared up. This patient felt so well at this time that he refused to take any more vaccine, although we advised that several more doses be given, explaining to the patient that cessation of symptoms does not necessarily mean thorough eradication of the infection. Examination of urine, August 16th showed: Specific gravity, 1015; no albumin, only an occasional leucocyte; no bacteria.

This case represents a typical acute pyelitis. The effect of the vaccine here was most striking; the ideal negative and positive phases are shown most beautifully.

CASE II.

Miss O., age 28. Patient gave a history which indicated a chronic pyelitis, with remissions. At the time we first saw her she had had a severe chill; her temperature was 104. Urination was very frequent; excessive pain on voiding, especially terminal pain referred to the meatus; great prostration. The right kidney was very tender to pressure. Examination showed colon bacilli and streptococci, and pus in abundance. Both streptococci and colon vaccines were used. Decided reaction after the first dose; moderate reaction after the second; little reaction after the third dose. Improvement in symptoms was rapid and consistent. No symptoms after the third dose, but patient consented to take three additional doses. This patient has never had a recurrence of symptoms. She has since become pregnant and has manifested absolutely no renal disturbance.

CASE III.

Mrs. E. Clinical history almost precisely

the same as in previous case. Bacteriological examination showed a pure culture of colon bacilli. We used a stock vaccine in this case with most satisfactory results, eight doses being administered.

Especially in colon infections, the vaccine should be used long after the clinical symptoms have disappeared, as it is most difficult to eradicate a bacteriuria due to the colon bacillus.

CASE IV.

Mr. F., age 61. Patient has sustained a fracture of the right arm and the left thigh, which confined him to bed a long time. During this period he developed decided urinary symptoms. After taking numerous drugs internally and having the bladder washed out, for several weeks, we saw him in consultation, in February, 1911. He was voiding every hour in the day time, and four or five times at night. There was pain at the end of urination. Patient had lost a great deal of weight and there was great mental distress. Examination showed that there was no stricture, the urethra accepting a large sound with ease. The searcher revealed no stone. The prostate was not enlarged. There was slight tenderness over both kidneys. Examination of urine revealed pus in abundance, a few hyaline casts, 1.4 per cent albumin, and a pure culture of the colon bacillus. The patient's son has failed to preserve a very interesting chart. Suffice it to say that, after four doses of vaccine, which caused a rather decided reaction after the first dose, with temperature of 102.1-2 for one day, and only very mild reactions after the other doses, the condition cleared up most satisfactorily. This was a bilateral pyelitis of low grade. Whether the trauma lessened the tissue resistance and the colon bacilli then made a ready inroad, it is impossible to positively state.

CASE V.

Mrs. C., age 22. This patient was in the sixth month of pregnancy when we saw her in consultation. She had a chill, followed by fever and excessive sweats. There was great frequency of urination and pain. Examination of urine showed large quantities of pus, colon bacilli, and streptococci. The vaccine was used in this case with splendid results, the patient getting four doses of the combined vaccines. This patient has since been delivered of another child, with no recurrence of symptoms.

This is an example of pyelitis of pregnancy. Dridgen and Ross prefer to speak of these cases as the "pyuria" of pregnancy, and they likewise do not hesitate to administer vaccine to a pregnant woman.

CASE VI.

Mrs. M., age 35. This patient had been operated upon by one of our prominent surgeons, the procedure being a perineorrhaphy, trachelorrhaphy and suspension of the uterus. A retention catheter had been introduced and allowed to remain several days. The temperature did not drop to normal. There was nothing about the wounds to account for the continued fever. When the catheter was removed, the fever persisted and urinary symptoms developed. Urotropin was given and bladder irrigations were used, to no avail. We saw the patient in consultation on August 26th, 1911. At this time she was voiding very frequently, both day and night, great pain accompanying each act. There was tenderness over the hypogastrium and over the right kidney; expression anxious; tongue coated. Examination of urine showed a trace of albumin, pus in abundance, pure culture of colon bacillus. We advised the use of colon vaccine, and we append the morning and evening temperatures in this case, as we believe it to be sufficiently interesting.

August 26th, 7:00 a. m., pulse 100; temperature 100 1-2. 5:00 p. m., pulse 110; temperature 103 1-2. Vaccine given at 5:00 p. m.

August 27th, 7:00 a. m., pulse 96; temperature 100. 5:00 p. m., pulse 96; temperature 101 1-2.

August 28th, 7:00 a. m., pulse 90; temperature 98 1-2. 5:00 p. m., pulse 90; temperature 99. Patient feeling much better in every way.

August 29th, 7:00 a. m., pulse 90; temperature 98 1-2. 5:00 p. m., pulse 96; temperature 98 1-2.

August 30, 7:00 a. m., pulse 90; temperature 98 1-2. 5:00 p. m., pulse 92; temperature 99.

August 31st, 7:00 a. m., pulse 86; temperature 98 1-2. 5:00 p. m., pulse 86; temperature 98 1-2.

September 1st, 7:00 a. m., pulse 86; temperature 98 1-2. 5:00 p. m., pulse 90; temperature 99.

September 2nd, 7:00 a. m., pulse 86; temperature 98. 5:00 p. m., pulse 90; temperature 98 1-2.

September 3rd, 7:00 a. m., pulse 86; temperature 98. 5:00 p. m., pulse 86; temperature 99. Dose of vaccine given to-day.

September 4, 7:00 a. m., pulse 86; temperature 99. 5:00 p. m., pulse 90; temperature 99 1-2.

September 5th, 7:00 a. m., pulse 86; temperature 98 1-2. 5:00 p. m., pulse 86; temperature 99.

September 6th, 7:00 a. m., pulse 80; temperature 98. 5:00 p. m., pulse 84; temperature 98 1-2.

September 7th, 7:00 a. m., pulse 86; tem-

perature 98. 5:00 p. m., pulse 86; temperature 98 1-2.

September 8th, 7:00 a. m., pulse 80; temperature 98. 5:00 p. m., pulse 80; temperature 98 1-2.

By this time the patient had absolutely no symptoms, urination being normal both day and night. We advised further injections, but she insisted upon going home. We have since heard from her attending surgeon that the patient is doing well.

This was unquestionably an example of ascending infection, the bladder, and later the pelvis of the kidney, being involved. The trauma caused by the continued presence of the instrument, acted as a predisposing cause, the ever-present colon bacillus being the exciting cause. Dodgen and Ross state that "It is now known that most of the cases of 'catheter fever', which have been examined bacteriologically, are the subjects of an infection of the urinary tract. The bacterium concerned has either been the bacillus coli, the bacillus proteus or some allied organism. Treatment with a vaccine prepared from the infecting organism, in some instances, permitted the subsequent passing of catheters or sounds without causing untoward symptoms, and in other cases acted as a preventative of rigors."

CASE VII.

Mr. J. B. T., age 60. Patient had had urinary symptoms for years. Was operated upon in another city for supposed calculus of the bladder. No stone was found, but a persistent perineal fistula remained. Patient came under our observation in June, 1911. At that time he complained of excessive frequency of urination, both day and night, voiding as often as every ten or fifteen minutes; excessive pain during and at the end of urination. Patient was having frequent rigors, with temperature ranging from 101 to 103.

Examination of urine showed tubercle bacilli in abundance, colon bacilli, staphylococci and streptococci. We advised out-door life, nourishing diet, etc., and began the use of an autogenous vaccine in order to immunize the patient, if possible, against the mixed infection. This patient has now been under this regime for several months. He no longer has chills or fever, has gained 25 pounds in weight, holds urine now at least one hour, and has comparatively little pain. We will continue the use of the autogenous vaccine until the mixed infection is fairly well under control, and then begin the use of tuberculin.

CASE VIII.

Mr. W. This patient has had both testicles operated on for tuberculous disease, on the left side an epididymectomy being done, and on the right, a complete castration, with a

high division of the vas, the latter wound having never healed at the time we first saw him. This patient later showed decided urinary symptoms. When we saw him, in September, 1911, patient was voiding every thirty to forty minutes, with terminal pain; temperature 101 to 103, frequent rigors. Examination showed a very nodular prostate and some involvement of the seminal vesicles. Examination of the urine revealed tubercle bacilli, colon bacilli, staphylococci and streptococci. This was plainly a case of ascending tuberculosis of the bladder. We advised, in this case, the use of autogenous vaccine and the outdoor treatment. Patient had a very prolonged negative phase after the first dose, necessitating a reduction of the dose the next time. This patient has been getting the vaccine now for two months. He has gained 20 pounds, looks very well; temperature about normal, urinates once an hour, and the wound over vas has healed. We shall carry on the same line of treatment as in the previous case.

CASE IX.

Mr. T. Complained of frequent urination during the day time, also getting up once or twice at night; pain in the perineum and referred pains in the back, testicles and groin; some pain also on ejaculation; patient very nervous and depressed. Examination showed a very tender, enlarged, nodular prostate. By massaging the gland, a large quantity of purulent fluid was expressed, which showed pus and organisms, chiefly staphylococci—plainly a case of chronic prostatitis. Not responding to massage, irrigation, dilatation, etc., we began the use of an autogenous vaccine several weeks ago. Frequency, pain, depression have all vanished, although the urine is not yet clear and the massage fluid still contains pus. We shall persist in the use of the vaccine until no culture can be obtained. We believe that massage and irrigations should be used along with the vaccine in this case, because by massage we improve the circulation in the gland, and thus bring more of the medium which contains the leucocytes to the parts.

CASE X.

Mr. G. Patient had a slight urethral discharge and a perineal fistula. Examination of the urethral discharge and the discharge from the fistula showed only staphylococci. Examination with a bougie revealed no stricture. There was no enlargement of the prostate. Patient had had a gonorrhea with probably an abscess of Cowper's gland, the latter condition accounting for the fistula. Irrigation failing to accomplish anything, we used the staphylococci vaccine. Six doses were ad-

ministered. The fistula closed and has remained closed for three years.

CASE XI.

Mr. R. Patient had dull pain in perineum and persistent pus in urine. Examination revealed a large, boggy prostate. The expressed fluid showed pus in abundance and staphylococci. After being under our care for two weeks, this patient left the city for a long trip. During this time he developed an acute exacerbation of the prostatic trouble, characterized by frequency of urination, pain and slight haematuria. Upon returning to the city, as soon as the acute symptoms had subsided, we instituted the use of an autogenous vaccine, with massage. At the present time all symptoms have subsided, the urine is clear, and the fluid expressed by massage fails to show bacteria.

The foregoing cases will illustrate, in a measure, some of the lesions in which vaccine therapy will be found beneficial.

In conclusion, we may state that:

1. Vaccine, or bacterin, therapy is a most useful agent in the treatment of certain genito-urinary conditions.
2. It is essential to make an accurate diagnosis, and to determine, as carefully as possible, the offending organism.
3. The dose should be such as to give a decisive negative phase of not more than 24 hours duration, followed by a good positive phase.
4. The vaccines should be used after all symptoms have cleared up, as bacteremia may persist even after these symptoms have disappeared.

THE FACTORS WHICH CONTRIBUTE TO SUCCESS IN MODERN SURGERY.*

By JOHN R. WATHEN, Louisville.

In accepting the invitation to present a paper before this society, composed as it is of general practitioners from the country districts as well as specialists from the cities, I have endeavored to prepare a paper which would discuss those topics of interest to all of us.

The great success of modern surgery, especially in those centers where large clinics have developed, can be clearly traced to factors which only a few years ago, did not enter into a consideration.

The intimate association of good pathologists and clinical diagnosticians having perfected laboratory facilities, with the surgeon in his modern and well equipped operating rooms, has aided much in allowing operations

*Read before the Muldraugh Hill Medical Society, Elizabethtown, Dec. 14, 1911.

to be performed with success which only a few years ago were considered the impossible.

When men of national or international reputation report to-day their mortality as a certain per cent. for some new operation, we should not think for one moment that this low mortality can be even approached by the average operator and much less if his facilities for work are not the equal of the best.

This is a day when organization and system have demonstrated what can be done in any line of activity, and in surgery it is no less true.

The individual operator, no matter how skillful or how learned, has to be aided by modern hospitals and have associated with him others as aids who are trained to his own methods, what we have come to term teamwork, is the secret of success.

And furthermore the time has arrived when even in the narrow specialties there will arise men who are more proficient in certain operations than their fellows who are doing the same general lines of work.

The profession and the public are fast recognizing such to be the case and are referring their cases to no one surgeon for every operation; but rather picking certain surgeons to operate for certain special conditions.

This method works no hardship on any one, for instead of giving each operator a great variety of work, gives him the same number of cases, but most of the kind he has devoted the most time to and is from his increased experience better able to perform.

We are accustomed to associate the names of our most prominent surgeons with the line of work which has made them famous. Their names are synonymous with the diseased condition with which they have most worked.

If asked to name the most important factor which contributed to success in modern surgery, I would unhesitatingly answer that it consists in the preparation of our patients before operation.

By this is understood the careful diagnosis and preliminary treatment, examination of the urine, the functional activity of the kidneys, from collected specimens from each kidney obtained by ureteral catheterization, etc., all of the utmost importance in many cases.

The X-ray diagnosis and the von Pirquet skin reaction for tubercular lesions are all of immense value.

The patient's heart, blood pressure and differential blood counts are now always considered before any difficult or dangerous surgical procedure.

It is not my purpose to go into details concerning each of the examinations as they should be familiar to all and I wish to discuss more general subjects.

It would not be far from the truth if I

were to say that about two-thirds of the cases for operation which come to the city from the country arrive on the afternoon train accompanied by their family physician and an early operation on the following morning in order that the doctor can return home and lose as little time as possible from his work at home.

This is hardly an exaggeration and is only too often the case for the best results.

Would it not be far better for the physician to send his patient to the surgeon and after he has carefully gone over the case, made analyses and examinations as needed, then let the surgeon notify the family physician and with little loss of time he could be present at the operation.

This would bring a result far better for both the patient and the doctors.

Another important factor for success is for the anaesthetic to be administered by one who practically does nothing but this class of work. The time has long since passed when any Tom, Dick or Harry should be allowed to attempt this most important part.

Likewise the anaesthetist should be equipped for all the various types of anaesthetics and be well paid for first-class service.

A large percentage of my cases I am now operating upon under nitrous-oxide gas and oxygen administered together with a special apparatus.

The habit of some surgeons to run to the country to do any and all classes of operations when they receive a call has placed those surgeons on the basis of the itinerant spectacle fitters who travel far and wide.

Of course there are exceptional cases of emergency which demand operations at the patient's homes in the country, but it is safe to say that 90 per cent of the so-called cases could be far better treated if brought to a well appointed hospital and well cared for after by the surgeon himself than left to the unaided family physician at home.

If a surgeon has any practice it is very difficult for him to leave a dozen or more cases in the hospital; cases which need his attention; to go to operate on one other out of the city.

With increased transportation facilities as we now have there is little or no excuse for cases to be operated upon in the country.

The mortality for these operations done at the homes is alarmingly high and it only brings surgery into bad repute.

Nor is this work appreciated or paid for as in the case when brought to the large city infirmaries. When a patient is too sick to be brought to the city, I believe that they are too sick to be operated upon in their home where the after-treatment will not be the best.

Nowhere is this truer than in the modern treatment of bad cases of appendicitis when

the Fowler-Murphy proctoclysis after treatment method is a necessity to save the patient's life.

And lastly, let us consider another very important factor for success, i.e., the advising surgical aid in the earliest stages of the disease and not waiting until all hope of a radical cure has passed.

Cancer and many other surgical conditions are curable if diagnosed and removed by a timely operation. It is the seeing of the delayed cases and the attempts to cure by operation that has often brought surgery in disrepute.

The laity judge us only by the results and it behooves us to have the lowest possible mortality and the largest percentage of permanent cures.

The diseased conditions which are now treated with success by surgery, but which formerly were considered as belonging to the internist, are even increasing and the field for newer operations and better results is ever widening.

The future depends upon the proper co-operation between the family physician and the surgeon, and any exchange of ideas from either for the general betterment of conditions should be most welcome.

CLINICAL CASES.

REPORT OF CASES.

By F. T. FORT, Louisville.

CASE I.—NEUROPLASTY OF THE MEDIAN NERVE; EXHIBITION OF PATIENT.

Patient M. T., colored; age 26, admitted to the City Hospital July 9th, 1911, at night. She had been cut across the right upper arm, transversely, and was bleeding profusely when the ambulance was called for her. She was taken to the hospital and two of the internes, Dr. Arnold and Dr. Clark, ligated the brachial artery and put a splint on the arm. The next morning when I examined her at the hospital I found that, in addition to the severance of the brachial artery, the median nerve had also been severed, as there was paralysis of all the muscles receiving their nerve supply from the median nerve. As there was every chance of infecting the wound, I would not attempt to re-open it and bring the ends of the nerves together. Another consideration that led me to defer suturing the nerve was the fact that collateral circulation had not thoroughly established itself. The radial pulse was completely gone and the arm cold and this, together with the chance of infection, caused me to defer going after the nerve until a later date. Three weeks later the wound had entirely healed,

with the exception of what is termed a skin sinus at the site of the injury. We anesthetized her, took her to the operating room, and cleansed the sinus with 1-1000 solution of bichloride. After the application of tincture of iodine and normal saline, we made an incision, found the median nerve, cut down to the end of it and verified the fact that it had been severed. Then I tried to find the distal end but was unable to do so until I brought the incision down, located the median nerve below and traced it upwards, the two ends being nearly three-fourths of an inch apart. Grasping the ends of the nerve with forceps, it was brought up from its bed and gentle traction made. I then cut the ends off and applied a through and through suture of No. 0 twenty-day chronic catgut, and three small silk sutures through the sheath of the nerve, drawing it together. The wound was closed without drainage, the arm flexed at right angles with a posterior plaster of Paris splint, and the patient put to bed. She remained at the hospital fifteen days after the operation, wearing the posterior splint. I saw her two days ago for the first time since she left the hospital. To-day she came to my office and I took her to Dr. Ravitch, who tried the faradic current on the arm and got a feeble response from the flexor muscles which are supplied by the median nerve, on the anterior surface of the forearm. I am inclined to believe that in the course of the next two years she will get a useful hand. I believe it is a fact that in those cases where the operation is deferred, the time required for restoration of the nerve is much longer than where it is done immediately. This patient can pick up a handkerchief, but has really very little grip. Sensation is more or less completely restored. I hope to make a continued report of this case later.

CASE II.—DOUBLE RESECTION OF INTESTINE FOR GUNSHOT WOUND IN A CHILD SIX AND ONE-HALF YEARS OLD; RECOVERY

Patient L. D., age 6 1-2 years; admitted to City Hospital July 28th, about eight o'clock in the morning. The history was that a little girl in her neighborhood had got hold of a 22 calibre rifle, loaded with a 22 "long," with the intention of shooting at some rats, and had accidentally shot this little girl, the bullet entering the body about 1 1-2 inches to the right of the umbilicus and coming out at the left of the coccyx, about 1 1-2 inches above the anus. She was in extreme shock, plus hemorrhage, and had very little pulse. She was hastened to the operating room and arrived there about nine o'clock. At this time the radial pulse was not perceptible. I had one of the internes prepare 600 c. c. of normal saline, with 15 drops of a 1-1000 solution

of adrenalin. Dr. Arnold gave the anesthetic and Dr. Clark assisted me in the operation. We made as rapid an entry into the abdomen as possible, and when the incision was made blood and fecal matter gushed out, showing that the patient had become exsanguinated. Dr. Melton opened one of the veins in the forearm and I asked him to give her 300 c.c. of the solution which he had prepared. The vein was very small, and after giving this infusion I told him to let the canula remain in the vein. Upon opening the abdomen the first thing we came across was this section, which, as you see, has several punctures. A clamp was put on and we did end-to-end anastomosis as rapidly as we could, paying especial attention to the mesenteric border and also making a mesenteric graft as it were, over that portion of the intestine where the mesentery was attached. The mesentery was brought up and sutured to the abdominal wall in front, covering as much of the anastomotic suturing as possible.

Upon reading the bowels a little further we came upon another perforated portion of the gut, I think it was the convolution just behind the first one resected, and it was necessary to resect this also. We took out four or five inches in one section and six or seven inches in the other. The same method of anastomosis was used and the mesentery fixed just as in the first instance. One or two additional isolated punctures were found which were closed with a purse-string suture. Prior to this, however, the patient had almost succumbed, and it was necessary to give her the other 300 c. c. of saline solution, 30 to 45 minutes after the first administration. After having completed the resections, and being unable to discover any more punctures, the bowels were washed thoroughly. I simply had the nurse pour in saline then introduced my hand and washed out the cavity the best I could, after which the abdominal cavity was filled with as much normal saline as it would hold, a drain inserted and the abdomen closed. The patient was then taken back to the ward and placed in bed, and I never expected her to rally again. However, by evening the pulse could be felt, the following day she was a little better, and on the second day she began to cry and cried almost continuously for three weeks. I do not think I ever saw a child cry so much. Nutrient enemias were given after the third or fourth day, and she did not get anything to eat until the twelfth day. About the first thing she was given was a small glass of beer. I tried to start her off on a little albumin water, but that did not suit her; she would not take panopepton, and I was unable to name anything that she could take until I mentioned beer, after taking which she began to get bet-

ter. I still thought she would die, however, until the 21st day, after which time I felt that there was some chance for her. She went along and made an uneventful recovery, and is now going to school. She was discharged from the hospital on August 31st. I called at her home to see how she was getting along this morning. The weather was too bad for her to go to school, but it was not bad enough to keep her indoors. She followed me to the car-line, a block distant, and then resumed playing with some other children.

CASE III.—GANGRENE OF THE UTERUS.

Patient C. C., colored; age 24; admitted to the City Hospital July 18th. She came in late in the afternoon or at night, giving a history that the bag of waters had broken something like a month previously, after which something had passed from her. It looked to us like a case of miscarriage. When she was admitted to the hospital, her temperature was 101 and she had a very foetid discharge from the vagina. Dr. Clark called me, and I told him to take her to the dressing-room, irrigate, and do a curettement. I went to the hospital to see another patient and arrived there just about the time he had this woman prepared, and made an examination. I could detect a mass on the right side, but thought it was some induration or tubal trouble connected with the abortion. We dilated the uterus, irrigated it and used spoon curett. She was put to bed and her temperature came down, as it usually does in a case of abortion. The next day she seemed to be in pretty good shape. On the 20th her temperature rose just a little, and she did not feel so well as she had the day before. That night I was called out of the city. About eight or nine o'clock she began to show evidence of a general peritonitis. Dr. Clark called Dr. Zimmerman, who saw the patient and made an exploratory incision. When he opened the abdomen this mummified foetus was found free in the cavity. I also exhibit the uterus, from the appearance of which it would seem that some one had tampered with the uterus, breaking the mucosa above, and that the pains had forced the foetus upward, dilating the fundus, and producing a gangrenous condition, or, that the fundus of the uterus was very thin and later became gangrenous and ruptured, allowing the foetus to go up into the abdominal cavity, followed by the development of a general peritonitis. The condition of this uterus feels almost like an hour-glass contraction. In doing the curettement, it felt just as the ordinary fundus does. Dr. Clark dilated sufficiently to get his curett in, but the uterus seemed to be fixed so that it could not be pulled down and the finger introduced. I believe that, had it been possible

to introduce the finger, the condition would have been recognized on the 18th, and operation would not have been delayed until the 20th, when it ruptured. The hour-glass contraction is just about midway of the uterine canal, and the space inside the uterus was just about as large as we usually find in a two or three months miscarriage. This is undoubtedly a case where the mucosa was broken, and the contraction of the uterus forced the foetus up into the fundus, making it thinner and thinner until finally it ruptured, and a general peritonitis ensued. Dr. Zimmerman did a Poro operation on the woman and she died three days later, I think, from exhaustion. She was probably about 6 1-2 months advanced in pregnancy.

DISCUSSION.

W. A. Jenkins: Just a word about this nerve case. I certainly think Dr. Fort did the right thing in this case, because it is a recognized fact that nerve regeneration is a possibility, provided the ends are brought together with the greatest care. I would suggest that, in this case, it would be a good idea to use both the faradic and galvanic currents, not too strong, every other day, about five minutes at a sitting.

J. Garland Sherrill: This is a very interesting series of cases. In regard to the nerve case, as has been said, it is almost impossible to prevent regeneration of a sensory nerve, while, on the other hand, it is a very difficult matter to get regeneration of a motor nerve, and yet we may succeed in doing this in a motor nerve, even after many months have elapsed since the ends were severed. The suturing must be done very carefully, although it is not always necessary to have the nerve ends directly in apposition. We may have a number of things between them; for instance, catgut, or a magnesium plate, and sometimes decalcified bone is used. A magnesium plate is considered the best because it forms a channel which will protect the nerve from interference by fibroblasts. If connective tissue fibres get in between the ends of the nerve, it will be difficult to get complete restoration of function.

I do not believe that the three weeks' time which elapsed between the injury and the operation in this case, will prevent restoration of function, unless degeneration took place much more rapidly than usual. In my opinion, not only should the faradic current be employed, as suggested by Dr. Jenkins, but the muscles supplied by this nerve should be stimulated by massage and friction, keeping them supplied with blood.

Bernard J. O'Connor: In my opinion, the most important case of the three reported, has been neglected in the discussion. Nerve surgery is not seen every day, but abortion cases are seen by all of us. The case mentioned by Dr.

Fort to-night is one of extreme interest, not only because of its rarity, but because of the fact that this patient had practically a double uterus, and the foetus was expelled upward through the thin layer of muscle and into the abdominal cavity.

One point that is impressed upon us by this case is that we should elicit a better history from these patients. In view of the history in this case, a larger uterus should have been shown by the curette; it should have reached a greater depth than it apparently did.

The question of septic abortion is one of the most important we have to deal with, especially in connection with curettage. Practically all of our very best authors are agreed that a sharp instrument should never be used in these cases; that only the dulllest kind of instrument should be used to remove portions of the afterbirth and other debris. The danger from a sharp curette is that all of the sinuses and blood vessels are opened up, so that the infection enters the vascular and lymphatic spaces, and in a short time, instead of a localized infection, we have a general infection to deal with. In cases of septic abortion where the offending organism is the colon bacillus, staphylococcus, etc., curettage is contraindicated. In an article by one of the very best authorities in Germany, he advises against the use of any instrumentation in cases of streptococic infection, even though some of the decidua structures still remain within the uterus. He holds that, in streptococic infections, it is better to wait until Nature has overcome the acute infection, and at a later date open the uterus and evacuate its contents.

B. F. Zimmerman: I think this case very forcibly emphasizes the fact that has been pointed out so many times, that we should not rely upon the curette but should use our fingers in all cases of abortion. In my opinion, it is the only way in which we can be absolutely certain that we have the uterus thoroughly clean, and the only way in which we can be absolutely certain that we are doing no injury to the uterus. These two facts, it seems to me, constitute sufficient argument against the use of an instrument in abortion cases. It is always possible to introduce the finger into the uterus in this condition.

I had not seen this case before I operated upon her. Dr. Clark made a diagnosis of general peritonitis, in which I concurred, and did an exploratory operation with the idea of establishing drainage. I was under the impression from the history that the foetus and placenta had passed, and that there was infection of the uterus which had resulted in a general peritonitis. Upon opening the abdomen in the median line we came immediately upon this bluish mass, which was somewhat confusing. I questioned whether or not we had a tubal pregnancy to deal with, but the tubes could both be palpated. Upon passing my hand below, I could feel the uterus which seemed

to be continuous with this mass, and in bringing it up the fundus simply tore away, and the foetus then made its appearance free in the abdomen. The odor was terrific, and was such as we usually get from gangrenous tissue. The abdomen was filled with pus. The hemorrhage was somewhat alarming, but this was controlled, and hysterectomy was then done.

It would appear that infection of the top of the uterus had occurred, which was very severe, resulting in a gangrenous condition, and the impaction of the uterine contractions upon the foetus forced it along the line of least resistance, which was through the gangrenous fundus of the uterus, and it simply pressed up and formed a sac above, which looked like a large gangrenous cyst on top of the uterus. Later it broke through the top of the uterus into the abdominal cavity, setting up a general peritonitis.

W. C. Dugan: I am glad that Dr. Zimmerman emphasized the fact that there is risk in using a sharp curette in these cases, although some have claimed that there is no danger of puncturing the uterus and getting into the abdominal cavity. I formerly used a sharp curette and thought that I could clean the uterus out thoroughly. On one occasion I did a curettage for another doctor, and about 48 hours later he telephones me that a three-months foetus had been discharged, although I was positive that I had emptied that uterus. Therefore, I believe that the only curette which should be used in these cases is the finger. We know exactly how much harm we are doing, if any, and we know positively when we have cleaned the uterus of its contents.

Edward Speidel: I would like to add a word to the discussion of this case. In cases of this kind, after the patient has been thoroughly anesthetized, the first thing that should be done is to insert the hand into the vagina and confirm the diagnosis, especially in a girl of this age, with a very thin abdomen. After the cervix is dilated, it should be easy to pass the finger into the uterus and ascertain whether or not it is empty.

In regard to curettage, I go even farther than the other gentlemen who have spoken. I think it is a great mistake that many of our standard text-books of the present day, after advising against the use of the curette in cases of abortion, end up by saying that "the only curette to use is the finger." In my opinion, emptying the uterus with the finger should not be termed curettage, and the books should simply advise against the use of the curette, and then say that the uterus should be emptied with the finger.

F. T. Fort, (Closing): I wish to thank the gentlemen for their liberal discussion of two of the cases reported. Nothing was said in regard to the double resection which I thought was the most interesting of the three cases.

As to the last case reported, I do not wish to be misunderstood in regard to the use of the cur-

ette. I do not believe that it is ever advisable to use a sharp curette in these cases, but I do believe, where we have a foetid discharge from the vagina, that irrigation, followed by curettement with a blunt curette will bring out debris that could not be obtained with the fingers.

Furthermore, it is a very hard matter to get a clear history from patients who come to the City Hospital. From the history obtained from this patient, I was led to believe that everything had passed. In the light of the termination of the case, I am satisfied that, in my examination with two fingers in the vagina (it was very hard to get the whole hand in, but I believe I did have it in after the patient was anesthetized), the mass that I felt was this distended necrotic fundus of the uterus, before it had ruptured.

I am glad that Dr. Zimmerman saw this case, for the reason that he hears out my own opinion of it. When the abortion was attempted the instrument was carried up far enough to injure the mucosa; then the rupture of the membrane let out some of the water and blood clots and the woman thought a miscarriage had taken place. Instead of this, however, there was what might be termed hour-glass contraction of the uterus, and when the pains came on they forced the foetus upward, against the fundus, which gradually became thinner and thinner until finally it ruptured. In using the spoon curette, when we thought we were scraping across the true fundus of the uterus, we were really against the contracted portion. Two days later this necrotic fundus became so weakened that it gave way, allowing the foetus and this putrid material to get into the abdominal cavity, causing a general peritonitis and necessitating immediate interference.

I would not call this hour-glass contraction as the term is used by obstetricians. It should rather be classed as a contraction filling up the body of the uterus and closing off the upper part.

SPLENECTOMY; EXHIBITION OF SPLEEN.

By IRVIN ABELL, Louisville.

The patient from whom this spleen was removed was a woman, 31 years of age; married, and the mother of one child eight years old. She has been married ten years. Shortly before her marriage she had suffered a fall from a haystack, and immediately following this she noticed the development of a tumor in the left side of the abdomen. After quite a long rest in bed this tumor disappeared, and during the succeeding eight months, during which time she bore a child, she had very little trouble except for occasional cramps, or colic, which usually subsided under rest in bed and the application of heat to the abdomen. Following her recovery from the birth of her child, she had, at irregular inter-

vals, attacks of colicky pain, with or without the appearance of a tumor in the left half of the abdomen. These usually subsided upon rest in bed and the application of heat. None of them were severe enough to require an opiate for the relief of the pain, and none confined her to bed longer than 36 hours until the one during which she came under observation. Five months previous to coming under observation she again became pregnant, the pregnancy being an unusual one in that she continued to menstruate regularly, having menstruated three weeks prior to coming to the city. She had suffered quite a good deal of discomfort since the pregnancy began, and during the menstrual period three weeks previously she had suffered cramps in the abdomen to such an extent as to necessitate confinement in bed for the entire three weeks. During these cramps the tumor again became very apparent, on the right side of the abdomen. When she was brought to the city her temperature was ranging from 100 to 101; pulse 90. The tumor could be made out distinctly and was apparently attached to the upper portion of the uterus, as I was unable to dislodge it from the right side. My own opinion was that, barring the possibility of an abdominal pregnancy, I was dealing with an ovarian tumor with a twisted pedicle. After getting her under an anesthetic the tumor could be made out very distinctly, and I still thought that I had to deal with an ovarian tumor, but upon opening the abdomen I found this spleen twisted twice upon its pedicle. The veins were enormously enlarged. The specimen still shows the tremendous dilatation of the veins. Dr. Baldauf was kind enough to make a microscopical examination of the specimen and found that the enlargement of the spleen was due chiefly, not to genuine hypertrophy, but to an increase in connective tissue stroma.

Difficulty in removing the spleen was experienced because of its close association with the tail of the pancreas, the pancreas being pulled around in the shape of a horseshoe so that its tail was to the right of the median line, and because of the infiltration and adhesions it was a difficult matter to identify and separate them without injury to the pancreas.

After the operation the woman's pulse settled down to normal and her further recovery was uneventful.

An examination of the blood, made before giving the woman an anesthetic, showed the following: Hemoglobin, 65 per cent.; red cells, 4,000,000; white cells, 12,000; practically but little change in the character of the cells; lymphocytes increased; transitionals, 4 per cent.; neutrophils, 66 per cent.; eosinophiles, 4 per cent.

This woman has had no trouble since going to her home and apparently—so her doctor thinks—is getting along as well as one could expect.

Upon looking up the literature upon wandering spleen, as it is termed, I found that quite a number of cases had been reported.

Bessel-Hagen reports a total of 43 cases of splenectomy for wandering spleen, with 40 recoveries. Schwartz reports a case similar to my own, in which a wandering spleen with a twisted pedicle was removed from a woman 36 years of age, at the fifth month of pregnancy, the latter suffering no interruption as a result of the operation. Asa B. Davis also reports a splenectomy for wandering spleen with twisted pedicle, occurring in the course of a pregnancy, without interruption to the latter.

There has been quite a bit of discussion relative to the preference of splenectomy or splenopexy. Several ingenious procedures have been devised with the idea of affording an anchorage for the loose organ. Among these, the most stable depend upon a niche in the peritoneum, or in the muscle structure of the lateral abdominal wall, placing the spleen therein and suturing the peritoneum closely around its pedicle. When a case of splenic prolapse comes to operation previous to the time of important change in it or its pedicle, the consensus of opinion at the present time seems to favor splenopexy. If, on the contrary, as in the case reported to-night, you are dealing with a twisted pedicle which has produced material enlargement of the spleen, and organic change in its pedicle, the operation of splenectomy, affording, as it does, a relatively safe recovery and sure relief, is to be preferred to any attempt at retention.

The spleens which have been removed owing to a twist of the pedicle, come under two classes; either acute torsion, in which event there is more or less gangrene, with more or less marked splenic degeneration; or, as in the case reported to-night, where from the history the torsion had existed between two and three weeks, and there is material increase in the connective tissue stroma, with marked organic change in the pedicle.

DISCUSSION.

J. Rowan Morrison: The enormous dilatation of the veins is certainly a very interesting feature of this specimen. Last summer I saw a spleen removed which, while not exactly of this character, had a pedicle not quite as long as the one Dr. Abell has exhibited. This woman had a mitral heart lesion and the congestion caused by this spleen gave her a great deal of pain, and the spleen was removed for that cause. In this case the spleen was covered with large quantities

of fibrin, a sugar-coated, or lardaceous spleen. Dr. Abell's specimen has not that appearance.

W. C. Dugan: I wish to congratulate Dr. Abell upon the successful termination of his case. He did exactly the right thing. In these cases of wandering spleen, especially where it is rotated upon its pedicle, the only thing to do is to remove it. An interesting complication of this condition was the attachment of the spleen to the pancreas. We find that referred to a number of times in the literature, and several fatalities from splenectomy have ensued from dealing with this attachment to the pancreas. Therefore, we must be very careful in dealing with this condition, just as Dr. Abell was in his case.

J. Garland Sherrill: I have been very much interested in this case. The diagnosis, of course, could hardly have been settled except by operation. I am especially interested in the subject because of the fact that I recently had a case in which I made diagnosis of the spleen lying in the lower portion of the abdomen, just above the brim of the pelvis, in a male. It is apparently very much increased in size and extends up half way between the pubic bone and the ensiform. Although somewhat mobile, it is held down in that position. After careful examination I came to the conclusion that this was the spleen, which had greatly enlarged, dropped down toward the pelvis and become attached. I recommended its removal and the patient said he would come back for operation, but he did not come and I learned that he had had very little trouble from it since that time.

As Dr. Dugan has said, I think Dr. Abell's management of this case was the proper course. If the spleen is enlarged and out of its normal position, very little can be gained by suturing it back in position. It will constantly sag down, and I think it is better for the patient to have it removed.

Geo. A. Hendon: Bearing more directly upon the feasibility of splenectomy, I wish to briefly report a case that I saw in 1905. I examined this patient for some unidentified tumor in the abdomen which I thought was an enlarged kidney, but upon making an anterior incision I found it to be an enlarged spleen which, when removed, weighed about five pounds. Microscopical examination was made by Dr. Hays, who reported it to be sarcoma of the spleen. That has been six years ago and the patient has enjoyed good health ever since, seeming not to be inconvenienced by the loss of the spleen. She made a good operative recovery.

Guy P. Grigsby: I would like to mention a case that I saw during my service as an interne. This was not a pathological condition but was the result of a bullet wound of the spleen, and the point I wish to particularly bring out is in regard to dealing with hemorrhage in such cases. This patient was a robust young fellow, who had been shot between the tenth and eleventh inter-

spaces on the left side. When brought to the hospital he showed no signs of shock or hemorrhage, but by the time we got him upon the examining table there was evidence of hemorrhage into the abdominal cavity. The abdomen was opened as soon as we could get the patient to the operating room. It was found that the spleen had been almost cut in two by the bullet, but no injury to any other viscera could be detected. The operator decided that the best way to get him off the table alive would be to control the bleeding by suturing the spleen, which he did, using catgut and apparently controlling the hemorrhage.

There was another very interesting feature of this case. The anesthetist was interrogated several times as to the condition of the patient, and each time reported that he was getting worse and worse, and finally stated that he was dead, the pulse and breathing having ceased. Being in close proximity to the heart, the operator decided to try massaging that organ. He did this through the diaphragm and, much to our surprise, the heart resumed its function, respiration was restored, and the patient actually came to life again. Towards the close of the operation, the operator again resorted to heart massage, the abdomen was closed and the patient was put to bed alive, but died on the second day, I presume from extreme exsanguination, despite everything that could be done including the repeated infusion of saline solution. Autopsy showed that there had been no further bleeding from the spleen. I think this case would have been a splendid one for direct transfusion, but this measure was in the experimental stage at that time.

C. W. Karraker: I would like to mention a case that I saw in the City Hospital at Detroit, during my service as an interne. A Polish woman was brought in with a large abdominal tumor. We were unable to obtain any history from her, but the staff surgeon determined to operate the next day, thinking she had a large cyst. During the night the patient died, and post-mortem revealed a rupture of the spleen, with a large quantity of coagulated blood in the pelvis.

SYPHILITIC TUMOR OF THE LIVER; REPORT OF CASE.

By J. GARLAND SHERRILL, Louisville.

In April, 1911, I presented this case to the society, and a full report of it will be found in the September 15th issue of the Jefferson County Number of the JOURNAL.

I have kept this man on inunctions of mercury up to the present time, and for some weeks he has been on the iodide of potassium, taking four teaspoonfuls of the saturated solution (approximating half an ounce) a day, and I have urged him to make it even more than this. In addition to this he receives an

inunction of mercury once a day. An interesting feature of the case is the material decrease in the size of the tumor which has taken place.

Some one has asked whether or not the Wasserman reaction has been made in this case. Dr. R. Hays Davis very kindly made this test for me in the primary study of the case, and I have not thought it wise to make one since that because he has been under active treatment all the time. At that time, however, Wasserman reactions made by Dr. Davis and by Dr. Cyrus Field, of New York, were reported negative. In this connection, I will say that one-third of the cases of syphilis of the liver, reported by D. M. Coplin in which the Wasserman test was made, gave a negative reaction.

DISCUSSION.

W. C. Dugan: I remember Dr. Sherrill's report of this case very well, and I must confess that I was mistaken in my views. I had no idea that this was a syphilitic tumor at that time. I remember having suggested that a Wasserman reaction should be made, not knowing that it had been made and was negative. He stated just now that the test had not been made since putting the patient upon active treatment. It is my understanding that the Wasserman reaction will be obtained after the administration of iodide of potassium in these cases, and when the doctor has another test made I should like to hear the result. I am certainly glad to have seen this patient again.

W. F. Boggess: To show the fallacy of diagnosis in these cases, I would like to mention a case that was brought here from Owensboro a number of years ago. I saw this man and I think Dr. Cartledge and Dr. Bullitt also saw him. This patient had a tumor in very much the same location as in Dr. Sherrill's case, and we all decided that it was a sarcoma of the liver and inoperable, and told the boy's father to take him back home and make him as comfortable as he could. He then fell into the hands of one of our homeopathic friends who began the use of iodide of potash and mercury, with the result that the tumor entirely disappeared.

I think possibly we have syphilitic tumors of the liver more frequently than we suppose. I would say that, if there is any special field for salvarsan, it would be in this condition. If this patient has not been given salvarsan, I should think it would be worthy a trial.

E. S. Allen: I can see no reason why we should not get a positive Wasserman reaction in a gummatous condition of the liver, where there is an active syphilitic process going on. I think the so-called syphilitic livers in which we get a negative reaction are really cases where the syphilitic toxin has become inert, the growth of fibrous tissue stimulated, and the tumor is

simply an overgrowth of fibrous tissue. In such a condition we would hardly expect to get a positive Wasserman reaction, but in a gummatous condition of the liver, with an active syphilitic process going on, I see no reason why the Wasserman reaction should not be positive in every case. We know that in active syphilis, where large doses of iodide of potash are given, it seems to liberate the encapsulated syphilitic areas. Therefore, I should think that, after giving this patient large doses of iodide of potash, having discontinued mercury for a few weeks, a positive reaction should be obtained.

J. Garland Sherrill, (Closing): I have not tried salvarsan in this case, wishing to first confirm my diagnosis and then to show the verified diagnosis to the society. Having done this I am now willing to have some of my friends try treatment with salvarsan.

I have been watching this patient rather closely and trying to keep him on active treatment, but during the early part of the treatment he dropped out of my sight for three weeks during which time he said he had not been taking the treatment. He has done so well under the combined treatment that I have been loath to make a change, but I think it would be well worth while to try an injection of salvarsan and see if it will not have a more rapid effect upon this growth. It has certainly been decreasing very rapidly during the past month.

HYPERNEPHROMATA; EXHIBITION OF SPECIMEN.

By WILLIAM H. WATHEN, Louisville.

This specimen is a large, so-called hypernephromatous kidney removed this morning at St. Anthony's Hospital, from a woman 36 years old, referred to me by Dr. J. M. Morris.

Five years ago she began having blood in the urine, but it was not abundant and would not continue at any one time for more than a few days, and sometimes did not return for many months. The intervals gradually grew shorter, and at each recurrence the blood was more abundant and continued longer. Recently blood has been in the urine almost continuously; sometimes abundant, again just enough to stain the urine, with an interval of from a few hours to two days. The urine was sometimes nearly the color of pure, fresh blood, but at no time were any clots of blood present.

During these five years she had enjoyed relatively good health, and until recently had lost but little flesh; at this time being comparatively spare, weighing about 110 pounds, her normal weight being about 140. While the loss of blood and flesh had materially changed her general appearance, she had no cachexia, or any symptom that indicated well

developed malignancy in any organ or structure. She was cheerful, ate well and slept well, and was never confined to her bed except when during the presence of much blood in the urine, she was advised by her attending physician to remain in the recumbent posture.

Dr. Morris had seen her but a few times during the five years, and had not until four weeks ago made a careful examination. He then outlined a large tumor in the region of the right kidney extending from under the ribs down to crest of the iliac spine and two inches below and an inch to the left of the umbilicus. The anterior surface of the tumor was even and relatively soft, while the posterior surface was inelastic, irregular and hard. The tumor was easily movable with apparently no adhesions. Pulse and temperature normal.

The findings in the urinary analysis by Dr. E. F. Horine are as follows:

"Quantity in 24 hours, 944 c.c.; color, reddish brown; sp. gr. 1.019 (corrected); reaction acid; sediment present; serum-albumin present; glucose absent; urea, 14.16 gms; blood present; bile absent; total solids, 41.8 gms.

Microscopically the urine contained a few conical and caudate epithelial cells and squamous cells; no crystals; an occasional hyaline and granular cast; erythrocytes; pus cells; no tubercle bacilli."

The bladder functions were not disturbed, the urine was passed at proper intervals, and was about normal in quantity.

Diagnosis, hypernephroma, and as no metastasis could be detected, the removal of the kidney through an abdominal incision was advised. The diagnosis was based upon the direct subjective and objective findings from which could be excluded primary carcinoma or sarcoma and renal calculi or tuberculosis, about the only disease to be considered.

In a pathological examination by Louis B. Wilson, of 40 tumors of the kidney, 32 were hypernephromata, 2 sarcomata, 3 papillo-adenocarcinomata, and 2 flat-celled carcinomata secondary to stone. It will thus be seen that finally about the only tumor to be excluded was carcinoma, secondary to stone. Stone may exist in a kidney for an indefinite time and cause symptoms similar to the symptoms in this case, but an error in diagnosis would hardly occur unless carcinoma developed in the later stages and this is so rare as to be hardly worth considering. Of course stone could be excluded by the X-ray. Primary carcinomata or sarcomata could not continue in a kidney for five or more years. Tuberculosis was excluded by the size and physical characteristics of the tumor and the absence of bladder irritation and involvement, always

present before the involvement of the kidney is suspected. Then the hemorrhage is often absent and seldom great in quantity, also the absence of bacilli as shown in the examination of the urine.

An incision was made over the tumor in the outer border of the rectus muscle. The right lobe of the liver was in front of and to the inner side of the kidney, and extended two inches below the umbilicus and over under the left rectus. The liver was not adherent, was soft, and no metastasis in it or any abdominal structure. The left kidney had by compensatory hypertrophy increased one-fourth in size and was apparently normal, and there was no stone in the pelvis or ureter. An incision was made through the outer border of the mesentery of the hepatic flexure of the colon, and the kidney, the size of a child's head, carefully enucleated and removed after doubly clamping the pedicle. The ureter and the renal vessels were ligated with No. 2 chromic gut. There was but little loss of blood. The excess of peritoneum with much of the fatty capsule was removed and all exposed surface covered by suturing the cut edges, entirely obliterating the cavity from which the kidney was removed.

She left the operating room with no shock and a normal pulse, and is in the same condition now.

The belief that hypernephromata have their origin (Crawitz) in adrenal rests, or (Stoerk) from proliferation of the adult secreting epithelium of the convoluted tubules, has not, and probably cannot be proven by any embryologic, histologic and pathologic working hypothesis. By considering these tumors of embryonic mesothelial origin, we can better explain than by any other hypothesis, their final sarcomatous character, histologically and in their mode of dispersion.

While further research may in a degree modify this belief as to the etiology of so-called hypernephromata in nephrogenic rests, of Wolfian origin, in the cortex of the adult kidney, at this time no other hypothesis is so satisfactory or explains so much. I think it may be clearly stated that hypernephromata always arises from embryonic remains in the cortex of the kidney, and in their origin have no relation to the adrenals.

They are manifestly more frequent than are all other tumors of the kidney, they are less rapid in growth than the primary carcinomata or sarcomata, and while if permitted to long remain, extensive metastasis results, if the diagnosis is timely made and the kidney removed promptly, the permanent result will be good.

CONTINUED REPORT.

The patient continued after the operation in nearly a normal condition, having but lit-

the elevation of temperature or acceleration of pulse. She made an uninterrupted recovery, and left the Hospital on the eighteenth day, feeling, eating and sleeping well. She is now much improved in her general appearance. She has gained flesh, has no pain, and the urine is normal in quantity and quality.

The following excellent pathologic report by Dr. E. F. Horine confirms the ante-operative and operative diagnosis:

PATHOLOGIC REPORT BY E. F. HORINE.

The specimen, a kidney, weighed 384 gms. Upon bisecting the organ, a tumor 7 cm. in diameter was observed occupying the center and projecting into pelvis of kidney. A yellow coloration was noted and blood exuded from the cut surface. The tumor was apparently entirely surrounded by a connective-tissue capsule. Specimens from various portions were hardened in alcohol and embedded in paraffin.

Hæmorrhagic areas were noted in all sections. The cells comprising the tumor were large, polygonal in shape and contained nuclei which exhibited considerable affinity for hæmatoxylin. Numerous large cells with multiple nuclei were observed. The cells were, for the greater part, grouped in masses and were surrounded by varying amounts of connective tissue. In some areas the tumor cells formed apparent alveoli, the alveolar lumen being filled with blood.

Diagnosis—Hypernephroma (malignant).

The hemorrhagic character mentioned above is of very frequent occurrence in hypernephroma and at times this characteristic may be so pronounced that only by careful search through numerous specimens can unaltered portions be observed. In the present case unaltered portions were found, but not without exercise of care in going over the specimens.

The discomfort and dangers attendant upon renal calculus are too serious to warrant any treatment but the most radical.

Few measures have proven as serviceable in erysipelas as ichthyol in 10-20 per cent. solution, or ointment.

Dazzling diamonds and loud talking vests are not as essential to professional success as some of the younger urologists seem to think.

Do not permit the withdrawal of a filiform whose introduction has given great difficulty, until it has remained within the urethra sufficiently long to well open the contracted point.

REPORT OF THE JEFFERSON COUNTY MILK COMMISSION.*

The Milk Commission makes its sixth annual report and desires to say that the Commission's work has grown proportionately with the amount of dairy products produced, and this has entailed an increased amount of work in the Secretary's office. We recently have taken in a new dairy, making seven under the Commission's supervision.

The early part of the year the milk from one of the dairies ran such a continued high bacterial count that the dairyman was suspended for some weeks, in fact, he was not allowed to resume delivery until he had shown conclusively, after several bacterial counts were made, that he could produce milk complying with the Commission's requirements. It is interesting to say that the trouble was found in sterilization plant, and after he put in a new sterilizer his count has been persistently low; and there has been absolutely no trouble from that dairy since. During the heated period of the summer there was very little trouble in keeping bacterial content low.

One of the most serious problems we have had to contend against is the butter-fat content of the cream. We have had a number of the dairymen unable, apparently, to keep the butter-fat up to 20 per cent. (Commission's requirements), and after investigating the question pretty thoroughly, we found it a hard matter for the dairymen to so set a separator that it will insure a uniform fat content. If they set it so as to run 20 per cent., or over, they are afraid that they will lose money by producing a cream too rich in butter-fat. If it is set with the idea of producing exactly 20 per cent. it frequently will run just a little below, so you can see that it is really a pretty nice point for the dairymen to overcome, and to fulfill the requirements of the Commission, and still not cheat themselves. The Commission has made a new requirement, that is, the minimum butter-fat must be 20 per cent. in cream.

In annual tuberculin testing and re-testing, we found only two reactors in all seven herds, both of which were slaughtered, and one of these failed to show any tubercular lesion—the first one that was killed that had reacted that did not show the tubercular process somewhere.

Your Secretary attended the American Association of Medical Milk Commissions in Philadelphia last May, and (with all due modesty) I think the Jefferson County

*Read at the Annual Business Meeting of the Jefferson County Medical Society.

Medical Society's Milk Commission had as good report as was made during the meeting.

At the National Dairy Show at Chicago recently, No. 6 Certified Dairy won first premium, both on milk and cream, and was given the highest score ever given by the government. Milk 99.4. Cream 98.8.

The American Milk Commission will meet in Louisville the latter part of this coming April. The Commission would like to urge all the members of this County Society to attend these meetings if possible. The Milk Commission has been able to maintain itself, and would have a small surplus in the treasury if the dues to the Commission were paid. The Secretary has some trouble in collecting these dues occasionally, but there has never been any loss.

Very respectfully submitted,
BEN CARLOS FRAZIER, Secretary.

BOOK REVIEWS

The Internal Secretions and the Principles of Medicine.—Two volumes, by Charles E. De M. Sajous, Fourth Edition, 1911, F. A. Davis Co., publishers, Philadelphia, Pa.

The first volume of this work was published in 1902, the second in 1907. Revisions were made in 1908, 1909, and the last in 1911. As nearly a decade has elapsed since Sajous work was given to the profession, an acquaintance with it of a large part of the profession is assumed. That he has devoted many years of conscientious labor; that he has brought into that labor the richness of a great experience, the logic of an analytical mind, the style of a ripe scholar, and the enthusiasm of an original investigator, is but stating well known facts. If it was thought, by the conservative at the time of the first publication, that the enthusiasm of the author carried him rather far afield, subsequent investigations by both the author and others laboring in this hitherto rather untilled pathological biology, must have convinced him that Sajous was in reality a pioneer in this particular contribution to normal biology.

The fundamental principles upon which the author's views are based may he tersely told: The thyroid supplies the blood with a secretion which sustains the functional activity of the anterior pituitary body. The pituitary gland stimulates the secretory functions of the adrenals through the suprarenal nerves. This trio constitute a system through which cardiac action, respiration, and general cellular oxidation are maintained. Optimistic though the author is, he says of his conclusions, submitted in the second volume, in the preface to the third edition: "The work introduces no elixir of life, no universal panacea," pleading, rather, for an intelligent acquaintance with, and the judicious use of, reme-

dies old in service, but with the pharmacological action of which too large a number of doctors are too little informed.

The chief interest centers around Volume I, in which a close analytical study of ductless glands in morbid processes is found. The most important change in this last edition is the elimination of practically 400 pages which had been devoted to a discussion of the physiological aspects of the thyroid gland, and replaced by a discussion of what the author deems of more practical value to the practitioner; in other words, he has elected to assume that his postulates are accredited, and that the elementary principles and laboratory findings are no longer necessary. Chapters 3, 4, and 5, for instance, are entirely new material, and are devoted to a consideration of the thyroid and parathyroids along similar lines to those with which the adrenals are treated in Chapters 1 and 2; namely, that many morbid conditions so seriously interfere with the functions of these glands, that they at least show a "lethal trend," and are often fatal; and this in addition to a discussion of such conditions as Cretinism, infantilism, myxoedema, etc., due to diseased conditions of those organs primarily. Especial emphasis is laid upon the results of insufficient action of the thyroid and parathyroids, tending to show the causative relationship existing between those groups of symptoms which are rather illy defined as neurasthenia, rheumatism, obesity, auto-intoxication, etc. The author contends also that many cases, mentally defective, are suffering from hypothyroidism.

In Chapter 11 the author presents a rather interesting theory of immunity. He thinks that toxins, bacterins and vaccines excite the thyroid-adrenal center, which he recognizes as the immunizing center; that this, in turn, increases the production of phagocytes and stimulates the adrenals, thyroid and parathyroids, resulting in an increase of "thyroxidase," and "adrenoxidase." The first he considers the opsonin and agglutinin; the last, the amboceptor; and these products, stored in the red cells, are discharged at the instance of the phagocytes, thus sensitizing and softening the bacteria to be "ingested by the phagocytes and deposited by their cytase (complement) and trypsin-like ferment, and this process continues as long as there are bacteria to produce toxins capable of exciting the adrenothroid center." Or, as the author summarizes: "The thyroxidase (opsonin, agglutinin) sensitizes and softens the pathogenic agent, while the adrenoxidase (amboceptor) oxidizes the phosphorus of the nucleo-protein granulations, liberating heat; the activity of the trypsin ferments (plasmatin and phagocytic complement) being correspondingly increased, the pathogenic agent is converted into benign and eliminable products."

tion.—A Manual of Pathology. By Guthrie McConnell, M. D., Professor of Pathology and Bacteriology, Temple University, Medical Dept., Philadelphia. Second Revised Edition. 12mo. of 531 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1911. Flexible leather, \$2.50 net.

The purpose of this volume is not that it shall attempt to take the place of the more voluminous text books on pathology, but that it shall enable the student especially to rapidly acquire the salient points on the subject. To the chapter on Tumors has been added a number of changes, particularly concerning the classification. The chapter on the Thyroid Gland has been rewritten, the classification much modified and new material made use of.

Practical Treatment—Volume III.—A Handbook of Practical Treatment. In three volumes. By 82 eminent specialists. Edited by John H. Musser, M. D., Professor of Clinical Medicine, University of Pennsylvania; and A. O. J. Kelly, M. D., Late Assistant Professor of Medicine, University of Pennsylvania. Volume III: Otavo of 1095 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1912. Per volume: Cloth, \$6.00 net; Half morocco, \$7.50 net.

Eighty-one physicians have contributed to this volume. The contents of this book consist of monographs on the following subjects: Constitutional Diseases, Diseases of the Respiratory System, Diseases of the Digestive, Urinary and Nervous System, Muscles and Diseases of the Mind.

Clinical Diagnosis—Second Edition, Revised and Enlarged.—Clinical Diagnosis. A Manual of Laboratory Method. By James Campbell Todd, M. D., Professor of Pathology, University of Colorado. Second edition, revised and enlarged. 12mo. of 469 pages with 164 text-illustrations and 13 colored plates. Philadelphia and London: W. B. Saunders Company, 1912. Cloth \$2.25 net.

This volume presents clearly and concisely the various laboratory methods which are of use in clinical medicine. Each section has been carefully revised and much new material has been added to every chapter.

The chapter on animal parasites has been entirely rewritten and more than doubled in extent.

Among the many additions that has been added in this new volume may be mentioned, the anti-formin method for tubercle bacilli, detection and significance of albumen in the sputum, a simple technic for the diagnosis of typhoid fever by blood culture, the Wasserman reaction.

The Practical Medicine Series—Comprising Ten Volumes on the Year's Progress in Medicine

and Surgery. Under the general editorial charge of Gustavus P. Head, M. D., Professor of Laryngology and Rhinology, Chicago Post Graduate Medical School, Charles L. Mix, A. M., M. D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume X. Nervous and Mental Diseases, Edited by Hugh T. Patrick, M. D., Professor of Neurology in the Chicago Policlinic, Clinical Professor of Nervous Diseases in the Northwestern University Medical School, Peter Bassoe, M. D., Assistant Professor of Nervous and Mental Diseases, Rush Medical College. Price \$1.25. Price of the series of ten volumes \$10.00. The Year Book Publishers, 180 N. Dearborn Street, Chicago, Illinois.

In this volume the following subjects are discussed: Symptomatology, Neuroses, Diseases of the Brain and Meninges, Diseases of the Spinal Cord, Diseases of the Peripheral Nerves, and Mental Diseases.

Practical Medical Series, Volume IX.—Skin and Veneral Diseases, Miscellaneous Topics, Edited by W. L. Baum, M. D., and Harold N. Moyer, M. D. Price \$1.25. The Year Book Publishers, 180 N. Dearborn Street, Chicago, Illinois.

Constitutional Relations of the Dermatoses opens the first chapter. Special attention is given to syphilis and allied diseases. Under the title of Miscellaneous Topics are History of Medicine, Insurance, Medico-Legal Questions and Sociology.

Practical Electro-Therapeutics and X-Ray Therapy.—With chapters on Pathology, X-Ray and Eye Surgery, X-Ray in Dentistry and Medico-Legal Aspect of the X-Ray, by J. M. Martin, M. D., Professor of Electro-Therapeutics and X-Ray Methods in the Medical Department of Baylor University. In the Medical Department of Southwestern University, in the State Dental College, Dallas, Texas. Containing 219 illustrations. Price \$4.00. C. V. Mosby Company, Publishers, St. Louis, Missouri.

This book has been written for the student and general practitioner and is a valuable edition to the library of those who are interested in Electro-Therapeutics.

Technicalities have been avoided, the numerous photographs and skiagraphs are from the author's private collection and are introduced as practical examples of the efficiency of the methods described.

It is hoped that this volume will awaken a deeper interest among its readers in the use of electricity and X-ray by showing what may be done by a thorough study and careful application of the methods presented.

Principles and Practices of Physical Diagnosis—By John C. DaCosta, Jr., M. D., Assistant Professor of Clinical Medicine, Jefferson Medical College, Philadelphia. Second edition, revised.

Octavo of 557 pages, with 225 original illustrations. Philadelphia and London: W. B. Saunders Company, 1911. Cloth, \$3.50 net.

The second addition has been thoroughly revised as to text and illustration without departing from the original plan and scope of the book which deals with the principles of physical diagnosis and their practical application to the study of thoracic and abdominal diseases. New matter has been incorporated, chiefly in connection with the subjects of sphygmomanometry, nodal rhythm, pleurisy, and lobar atelectasis. A great many new illustrations have been added.

Diseases of the Skin and the Eruptive Fevers.

—By Jay Frank Sehamberg, M. D., Professor of Dermatology and Infectious Eruptive Diseases in the Philadelphia Polyclinic and College for Graduates in Medicine. Second edition, revised. Octavo of 573 pages, 235 illustrations. Philadelphia and London: W. B. Saunders Company, 1911. Cloth, \$30.0 net.

Dr. Sehamberg especially emphasizes diagnosis and treatment. The chapters on actinotherapy, Röntgenotherapy, and radium are particularly valuable, expressing, as they do, the very latest achievements in the use of these therapeutic agents. The cutaneous manifestations of all diseases are considered, not alone of the ordinary exanthematous fevers. The views expressed on all topics are conservative, safe to follow, and practical. The book is profusely illustrated.

Operative Obstetrics, including the Surgery of the Newborn.—By Edward P. Davis, M. D., Professor of Obstetrics, Jefferson Medical College, Philadelphia. Octavo volume of 483 pages, with 264 illustrations. Philadelphia and London: W. B. Saunders Company, 1911. Cloth, \$5.50 net.

This volume is abundantly illustrated and a complete bibliography has been added. Operative Surgery, in Obstetrics has reached a point where more complete elucidation is needed, this the writer has ably done, the various technic and individual methods of delivery are concisely and clearly stated.

Nervous and Mental Diseases.—By Archibald Church, M. D., Professor of Nervous and Mental Diseases and Medical Jurisprudence in Northwestern University Medical School, Chicago; and Frederick Peterson, M. D., Professor of Psychiatry, Columbia University. Seventh edition, revised. Octavo volume of 932 pages, with 338 illustrations. Philadelphia and London: W. B. Saunders Company, 1911. Cloth, \$5.00 net; Half Morocco, \$6.50 net.

This book has been written for medical students and general practitioners. The literature of neurology and psychiatry has been sifted by the authors, and such digest revised in the light of their own experience in practice and in teach-

ing. Each subject is presented clearly, directly and with brevity, despite the difficulty of condensing two great subjects within the limits of a single volume.

An unusual number of illustrations for each department has been added from the author's own material.

Currents of High Potential of High and Other Frequencies.—Second Edition.—By William Benham Snow, M. D., Author of "A Manual of Electro Static Modes of Application, Therapeutics, Radiography, and Radiotherapy," "Therapeutics of Radiant Light and Heat and Convective Heat," Editor of the Journal of Advanced Therapeutics, late Instructor in N. Y. Post-Graduate School and Hospital, etc., Scientific Author's Publishing Co., 329 W. 57th Street, New York City. Price \$1.00, net.

This work has been entirely rewritten, revised and enlarged. Forty cuts have been added, and the chapters on High Frequency Currents and Therapeutics have been revised and entirely rewritten. The work contains the results of the author's personal researches and investigations, and includes most that is valuable on the subject of High Potential Currents. The developments on the subject of hypertension and its treatment by the d'Arsonval current, as well as the employment of direct d'Arsonvalization in the treatment of infection, have been thoroughly considered in this edition.

Fourth Report of the Wellcome Tropical Research Laboratories at the Gordon Memorial College, Khartoum.—Volume A.—Medical. By Andrew Balfour, M. D., B. Sc., F. R. C. P. Edinburgh, D. P. H. Cambridge, Director Fellow of Royal Institute of Public Health, the Society of Tropical Medicine and Hygiene, and the Incorporated Society of Medical Officers of Health, etc. Published for the Department of Education, Sudan Government, Khartoum. Depots for North America, Togo Publishing Co., 35 West 33rd St., New York City.

It is almost impossible to exaggerate the importance of the work which is being accomplished by the distinguished group of scientific men associated with the Wellcome Tropical Research Laboratories, under the leadership of Dr. Andrew Balfour.

The thorough examination of the conditions of tropical life, as they present themselves in men, animals, plants and insects, is the task to which this great institution is devoted.

The Fourth Report of the Laboratories, which is now being issued, contains the facts, observations and discoveries brought to light during the last few years. Unlike the commentaries and digests which are so familiar a feature of the scientific press, these volumes contain the actual record, at first hand, of new contributions to the

solution of problems of deep and world-wide import.

Their value is further enhanced by the superb manner in which the knowledge, so laboriously gained, has been presented and illustrated. The expansion of the work of the Laboratories and the amount of new material collected during the last few years have rendered it impossible to issue the Fourth Report in one volume, and the subject matter has, therefore, been divided into two parts. The first part, Volume A, of which a complimentary review copy is being sent herewith for your acceptance, deals with the medical aspects of the work of research. Volume B, which relates to general science is now in the press, and will be issued shortly. Volume A presents the results of the bacteriological examinations carried out at the Laboratories. Pathological and other specimens from a wide area, and illustrative of many forms of endemic disease, have been the subject of investigation. Important papers have also been contributed on the work of the Sleeping Sickness and Kala-azar Commissions. The fallacies and puzzles met with in the course of blood examination in the Tropics form the subject of an interesting and well-illustrated article. An extended research on fowl spirochaetosis has demonstrated the important role played by the "infected granule" in this disease. Other papers include records of work on trypanosomiasis, human spirochaetosis, kala-azar, forms of cutaneous leishmaniasis, yeldt sore, diphtheria, human botryomycosis, veterinary diseases, etc. The interesting notes contained in the previous reports on sanitation in the Sudan are continued.

The two volumes of the Report, (A) and (B) together, contain 738 pages of letterpress and illustrations, many of the latter being in natural colours.

The price fixed for the Reports is as moderate as is consistent with the great cost of production, and any profit made will be devoted by the Sudan Department of Education to a special fund for future publications of the Laboratories.

In order to place the reader completely in touch with the latest phases of the whole subject, a third volume has been added as a supplement. It is entitled "A Second Review of Recent Advances in Tropical Medicine, etc."—a title which is amply fulfilled in the contents.

The last Reports were issued in 1908, and the announcement that a further instalment of the work was to be expected has aroused the keenest interest among students of tropical medicine and a very large demand is anticipated.

A Handbook of Medical Diagnosis—In Four Parts—By J. C. Wilson, A. M., M. D., Professor of the Practice of Medicine and Clinical Medicine in the Jefferson Medical College, Physician to Pennsylvania Hospital, Physician in Chief to the German Hospital, Philadelphia. 418 Text Illustrations and 14 Full Page Plates. Third Edition.

Thoroughly Revised. Price \$6.00. J. B. Lippincott Company, Publishers, Philadelphia and London.

This volume is arranged in four chief parts. First, Medical Diagnosis in General. Second, The Methods and their Immediate Results. Third, Symptoms and Signs. Fourth, The Clinical Applications.

Much has been rewritten and especially the articles on epidemic antro-poliomyelitis, beri-beri and pellagra.

Serum diseases and anaphylaxis in general have been considered, much of the section on diseases of the heart has been recast, and a section on the electro-cardiograph added. Many changes in diseases of the nervous system have been made. A number of new cuts have been added.

Syphilitic Lesions in the Bladder.—Asch has encountered three cases of true bladder syphilis and a large number of parasyphilitic bladder affections in the last twelve years, and he compares these experiences with the literature on the subject. The bladder is usually affected, if at all, during the third phase of syphilis. These syphilitic affections of the bladder seldom have a specific aspect and their true nature may be unsuspected. Gunmas often simulate papillomas and he suggests that it is wise to examine for syphilis in every case of papilloma of the bladder. Gunmatous growths cause manifestations like those from any neoplasm, except that they are liable to induce considerable hemorrhage; the hematuria is distinguished by its continuance from beginning to end of the urination, while with neer, even the syphilitic, the hemorrhage is more terminad. Treatment should be the general specific treatment without local measures. General treatment is liable to induce pronounced benefit in tabetic bladder disturbances. Asch cites forty-three recent publications on the subject of syphilis of the bladder.

Standard of Efficiency Required of Physicians.

—Tinkham says it would be a decided step in advance if there was an organization of state boards which required some standard of efficiency as a prerequisite to membership and which could have some influence in bringing about a more uniform standard of examination. It is difficult to see how the influence of state examination and licensing boards is to produce an elevating influence on medical education until they are composed of men who are as well qualified to examine medical graduates as the men who compose medical faculties are qualified to teach, and it is difficult to see how state boards can determine and maintain a satisfactory standard of efficiency for medical graduates unless these boards are composed of efficient men.

NO. 3

EDITORIAL

THE LATE WILLIAM A. ATCHISON.

A search of the old records of the Kentucky State Medical Society shows that Dr. Atchison was elected to membership in the Society at Lexington, on April 6, 1869. At this same meeting, he was elected Senior Vice-President and on the last day after Frankfort had been selected as the next place of meeting, it is recorded that "Dr. Atchison moved a reconsideration, and in a most eloquent manner extended a cordial invitation from the Medical Society of Bowling Green to meet in that place. The motion to reconsider carried and Bowling Green was by a unanimous vote designated as the place for the next meeting." It appears that Vice-President Atchison presided during the rest of this meeting. It is of interest that at this meeting a Committee was appointed to investigate the advisability of giving medicine by hypodermic injections, and that a Committee on Vital Statistics was created of which Dr. Charles Munn, of Nicholasville, was chairman.

The fifteenth annual meeting of the Society was held in Bowling Green, beginning April 5, 1870. The late Dr. H. M. Skillman, one of the most beloved and distinguished physicians our State has ever produced, had been re-elected President the year before but was unable to be present on account of dangerous illness, and Dr. Atchison presided as Senior Vice-President. It is of passing interest that there were twenty-four members present at this meeting and seven new members were elected during the meeting. It is to be noted that at this meeting chloral was first reported as a useful medicine. Dr. W. A. Atchison, of Rich Pond, was unanimously elected President, and it is stated that upon assuming the chair of President for the en-

suing year Dr. Atchison thanked the Society for the honor conferred in a brief and happy manner.

The sixteenth annual meeting was held in Covington with President Atchison in the chair. There were thirty members in attendance at this meeting. Upon motion of Dr. Kearns, who is still one of the most distinguished practitioners in Covington, a Committee was appointed to invite the State Medical Society of Ohio, which was then in session in Cincinnati, to take part in the proceedings of the Kentucky State Medical Society. This Committee consisted of Drs. Kearns, L. B. Todd, of Lexington, and David W. Yandell. The two societies seemed to have held a joint banquet. The total income of the Association for this year as reported by the Treasurer, Dr. L. B. Todd, was \$278.85. Dr. Atchison does not seem to have been present at any other meeting of the Society.

Dr. A. B. Cooke, of Nashville, formerly of Bowling Green, contributes the following sketch of the life of the late Dr. William A. Atchison, who was the oldest living Ex-President of this Association:

"The subject of this sketch was born in Warren County, Kentucky, on August 17, 1831, and died at Nashville, Tennessee, on December 18, 1911, in the 81st year of his age. For a number of years he had been troubled with a mild grade of arterio-sclerosis complicating a valvular heart lesion, but only within the recent past was there any noticeable impairment of his general health. Some three months ago he began to suffer with attacks of pain in the left chest, accompanied by embarrassed breathing, which he attributed to indigestion, but which proved upon examination, to be of cardiac origin. He was at once frankly advised as to the true nature of the trouble, and accepted the verdict calmly, continuing with perfect equanimity in the even tenor of his way until the call came. His

WILLIAM A. ATCHISON, A.M., M.D.

PRESIDENT OF THE KENTUCKY STATE MEDICAL SOCIETY IN 1870; SENIOR
VICE-PRESIDENT IN 1869; PRESIDENT OF THE NASHVILLE TENNES.
SEE ACADEMY OF MEDICINE IN 1888-9; AND A MEMBER OF THE
TENNESSEE STATE MEDICAL ASSOCIATION SINCE 1875;
DIED IN NASHVILLE, TENN., DECEMBER 18, 1911

mind remained clear, his carriage erect and vigorous, and his interest in life alert and earnest until the very end, death overtaking him while seated in his accustomed chair reading his morning mail.

"Doctor Atchison graduated in medicine from the University of Louisville about 1852, and at once began to practice in his home county, removing to Bowling Green, Kentucky, a few years later. He was a successful physician from the start, and rapidly built up a large and desirable clientele. On January 1, 1875, removed to Nashville, and formed a partnership with his uncle, Doctor T. A. Atchison. For the following twenty years the firm of Doctors T. A. and W. A. Atchison stood at the forefront of the medical life of this city, both in popularity and in high character of professional work.

"Doctor Atchison loved his profession, and retained an active interest in it to the last. He was a faithful reader of medical journals, and kept his library up to date in the department of general medicine, to which his practice was limited. At the bedside he was one of the most resourceful men the writer ever knew. His therapeutic armamentarium seemed inexhaustible. He never abandoned hope nor acknowledged defeat so long as a patient continued to breathe.

"Doctor Atchison also loved his professional brethren, and seldom lost an opportunity to attend medical gatherings. He was President of the Kentucky State Medical Association while still a young man, (in his thirty-ninth year), and was the third President of the Nashville Academy of Medicine, serving for the year 1888-9. During the whole of his life in the state he was a member of the Tennessee State Medical Association.

"As citizen, as friend, and as Christian gentleman, as well as in the capacity of physician, Doctor Atchison measured up to the highest standard. A man of unswerving integrity, firm in his convictions on all subjects, as strong men are and should be, conscientious, charitable, God-fearing—what more need be said of him? For thirty-six years of his active and useful life a familiar figure in the community which he early came to regard as home, loved most by those who knew him best, and honored by all, he will be missed from his daily walk of service to his fellowmen, and deeply mourned by many to whom he was counselor, benefactor, friend, and physician all in one.

"Doctor Atchison's wife died in February, and his only daughter in July, 1911, thus leaving him entirely alone. Necessarily he was lonely in spite of the loving interest of numerous friends. The reunion with his family to which he looked forward with longing and in

perfect faith came within the short space of ten months. Who shall say that it is not better so?"

IN DEPRECIATION OF THE NEGLECT IN GENERAL BY PHYSICIANS OF THE MEDICINAL TREATMENT OF DISEASE.

I.

THE TREATMENT OF MALARIAL DISEASES

The injudicious—as well as others—may smile at didactic aphorisms about disorders which are admittedly remediable specifically, just as common itch (scabies) has long been recognized to be amenable to sulphur applied locally and syphilis has been regarded as curable by mercurial salts. Nevertheless, I regard authoritative oraculism as very pertinent particularly regarding this subject for these reasons: (1) That the average family physician sees too little of malarial diseases nowadays in the Middle States, to enable him to continue thoroughly familiar with it; wherefore he is extremely apt to consider a case of mild aestivo-autumnal fever with abdominal symptoms to be appendicitis or extra-uterine pregnancy. I was highly amused about eighteen months ago at a bright young lawyer's account of his experiences in such an infection, in the course of which he narrowly escaped an operation for appendicitis in "The Athens of the South"—Nashville, Tennessee; (2) That I have for some years observed that almost without a single exception tertian fever patients are allowed to relapse and to re-relapse in conditions that should have insured their avoidance; and (3) That irregular manifestations of malarial troubles are so often overlooked by very reputable physicians.

It is so trite an observation as to be really undignified for one to have to say that with thorough use of the microscope for blood examinations and with the repeated employment of the Widal test, the diazo reaction, etc., there should be no more discussion about typho-malarial fever, nor any uncertainty, at least for long at a time, as to what ails a given patient in the States referred to. H. F. Harris has settled all that for years to come.

Knowing definitely the nature of his task, the practitioner inexperienced in the treatment of malarial diseases with only current standard text-books to guide him, will find himself at the outside unprepared to afford his patients either comfort in their paroxysms or protection from their recurrence.

In the paroxysms, he may be misled into treating the high temperature (which is quite the commonest and assuredly the deadliest medical high crime and misdemeanor!) with one or more of the antipyretics which are

both as numerous and as deadly as the plagues of the Egyptians *apud* Moses. Further, his misconception of his duty as a curer rather than as a palliator of suffering, may lead him to administer some of the newer and (alleged)—especially by their vendors) little harmful analgesics, to relieve the severe pains in head, limbs or loins. I have many times seen delicate persons brought to the very threshold of death's door by these insidious products from Germany. I incurred a simple tertian infection at Palatka, Florida, in September, 1909, after having visited unscathed the majority of the dangerous regions of the earth where the deadliest malarial diseases prevail. Being at that time much out of health from neurasthenia and other disorders, I was greatly upset by the paroxysms, so I feared to attempt to treat myself. In fact, my occasional delirium would alone have prevented it. But I found that I had actually to order my attendants not to administer any anodynes of a synthetic nature to me, although they were more than once ordered by my good friends, the local practitioners.

Comfort of relatively high degree may be afforded in the cold or shaking stage of an ague fit, as chills were long called in Great Britain, by a large dose (30-45 minims) of spirit of chloroform, which may be repeated within fifteen minutes, if required. Capsicum in thirty-grain doses in pills will often relieve most of the symptoms of this stage; and I have not found it to give much, if any, local trouble in the stomach, although it should not be risked, if there will have been vomiting or any other contraindication. (It will be referred to later as an anti-malarial of considerable power.) These failing, a hypodermic injection of a full dose of morphine or else a full dose of opium, preferably in the form *parvorie*, should be administered. If one of the foregoing remedies will have been used with effect, the hot stage will very likely be passed in sleep and will thus require but little attention for the patient.

It is repeated for the sake of emphasis that no treatment other than local refrigerants should be used in it. The temperature is sometimes, particularly in delicate women, so high as to appear deadly; but deaths from hyperpyrexia in malaria are very rare; and I, for one, do not consider them a whit less terrible than those from poisoning by Darmstadt and Berlin products.

Henceforth opinions differ and plans of treatment diverge.

I consider that the nature of the *causa causans* of these diseases must necessarily guide.

In young and robust patients, it will do no real harm, just as it will cause them little real inconvenience, to saturate them with

quinine. Older persons with circulatory troubles, either incipient or declared, will probably survive such treatment; but it will be to curse their physician bitterly for the misery that he will have caused them through tinnitus, etc.

I prefer to try merely to throttle the next paroxysm; and I think that this may practically always be done with not more—nor with much less—than forty grains of a quinine salt, and I greatly prefer quinine muriate or hydrochlorate. However, the life-cycle of the *plasmodium malariae*, in its human host, makes this procedure a matter of some exactness in using the most elective preparation. In infections that have progressed measurably, so that the paroxysms come about noon, it has been sufficient in my experience to get the last of the doses making up the forty grains administered about six hours before the time for the paroxysm to be averted. The other dose (or doses) should not have preceded this final dose by a greater interval. Hence, if there be any uncertainty about their retention or about the absorption of these doses, hypodermic administration should be resorted to. Muriate of quinine and urea is now so common as a local anaesthetic that its non-employment by deep intra-muscular injections well distributed should not be countenanced professionally; but, of course, the dose should be reduced to suit the method. The danger of abscess after using quinine salts *sub cut* has been due, I feel sure, to: (a) Using insoluble or little soluble salts in large volumes of water; (b) Injecting such solutions under the skin in relatively non-vascular areas; (c) Imperfectly appreciated principles of asepsis. Proof of the foregoing explanations are afforded, I believe, by the work of the U. S. Army Convalescent Hospital on Corregidor Island, Manila Bay, where thousands of hypodermic (or, rather, intra-muscular) injections of quinine have been administered without an abscess.

But it will not suffice to have forestalled a single paroxysm in an intermittent fever patient; it will be wise to prevent at least two more exactly as the first. I then, noting as carefully as may be done from the history of the first paroxysm, prepare for treating the patient on the *twenty-first day* from that date exactly as if it were "chill day"—as it will, in many cases, actually prove to be.

W. F. A.

(To be continued.)

Eczema of the palms and soles demands the most energetic treatment. A prime necessity is to get rid of the thick epidermis which may be accomplished with *sapo viridis*.

RECTAL ALIMENTATION.

Rectal alimentation is discussed in the therapeutic department of the *Journal A. M. A.*, (January 13, 1912, p. 114). It is pointed out that when a patient is unable to take an adequate amount of nourishment by the stomach, or, having taken it, is unable to retain or digest it, the physician is obliged to try to assist nutrition by way of the rectum. The work of David L. Edsall and others shows that very favorable results must not be expected but that nevertheless some nourishment is absorbed in this way.

At the present time there seems to be good reason to believe that ordinary food, undigested, is not very freely absorbed by the rectal and colon mucous membrane; consequently most practitioners who employ this form of alimentation use a predigested food. Milk and eggs are readily available for this form of nutrition. A formula attributed to H. C. Wood is as follows:

R.	Gm. or c.c.
Pancreatin	30 or gr. v.
Sodii bicarbonatis	1.30 or gr. xx.
Aquae	30 or fl. zi

To this may be added the whites of one or two eggs, and the whole kept at a temperature of 110 F. for from one to two hours, the longer time permitting more complete digestion.

Besides water, peptonized food, and salt, alcohol is often an ingredient of a nutrient enema, and is frequently indicated.

Observations would seem to show that the most important ingredients of a nutrient enema are water, sodium chlorid, dextrose, alcohol and peptonized milk and egg. Of course these are not all to be combined at one time, but a judicious combination must be selected according to the individual indications in each case.

Before the first nutrient enema is given the rectum should be washed out by an enema of simple warm water or normal saline solution. Usually one pint of water will be sufficient for this purpose. This cleansing enema should be administered one hour before the nutrient enema. Care should be used not to give it too frequently, lest the mucous membrane of the rectum become irritated so that it will not retain the nutrient enema. The nutrient enema should not be administered either cold or hot, because cold or hot fluids are likely to stimulate the muscular coat of the rectum and lead to their expulsion. The best temperature is between 95 to 105 F. The injection should be administered with a fountain syringe, and should be allowed to enter the intestinal canal slowly. A long tube should be used, so that the fluid may be deposited about the sigmoid flexure or as near to that part of the large intestine as

possible. The fluid absorbed at this point passes into the portal vein and goes to the liver where it undergoes assimilation. Furthermore, the higher up in the large intestine the enema is placed, the greater chance is there for reverse peristalsis, and consequently better digestion and absorption.

The amount of each enema must vary according to the tolerance of the lower intestine of each individual patient. Some patients can retain a pint of warm fluid, but for most patients 6 or 8 ounces is a safer amount to use.

The patient should, of course, be lying in bed while the enema is being administered, and should retain the recumbent position for at least an hour after the operation is completed.

CONSULT YOUR PHARMACIST.

The matter which appears on another page under the heading of "Prescription Nonsense" makes *apropos* the recommendation which recently was made in a paper read before a pharmaceutical society, in which it was stated that every physician should have a pharmacist whom he can go to for advice. This paper by W. A. Puckner, Secretary of the Council on Pharmacy and Chemistry states: "Physicians need pharmaceutical advisers—those whom they may consult concerning desirable methods of preparing medicines for administration, their incompatibilities and similar questions, upon which it is difficult for physicians to keep posted." The speaker noted that "many physicians have been inclined to forsake their corner druggist, because he has been tried and too often found wanting, and have pinned their faith to pharmaceutical manufacturers and promoters of specialties and their detail men. Dependence on the specialty proprietors has, however, been disastrous—so disastrous that well informed physicians will have no more of the physician's dependence on proprietary detail men."

After pointing out how disastrous has been the physician's dependence on proprietary medicines the paper states that every reason exists why physicians should go back to the writing of individual prescriptions to be compounded by a pharmacist. The paper then continues: "Happily, there are signs that pharmacists are awake to the tendency of the times and are making efforts to devote more attention to the professional side of their business; and, as a result, there is a tendency on the part of physicians to go back to the old times, and once more get in touch with their druggist. The pharmacist, however, must realize that physicians need *real pharmacists* as advisers and not druggists, who, while prominent at 'Get-together dinners,'

with talk of 'U. S. P. and N. F. Propaganda,' neglect their prescription counters to prepare grewsome 'patent-medicine' displays and advertising dodges in their front windows."

PREScription NONSENSE.

Referring to a paper on the treatment of gastric ulcer the therapeutic department of the *Journal A. M. A.* (Jan. 6, 1912, p. 34) says: "The general acceptance of the prescriptions of men of renown which were quoted by the author is, however, to be deplored. These prescriptions are neither advisable nor valuable. The same deplorable prescriptions were copied semi-editorially by another journal, the quotation not giving the valuable parts of the original paper. The fact that a man is of great ability and of great reputation is no proof of his ability to write sensible prescriptions or to treat a disease or condition scientifically. Able practitioners are many times divided into two classes: those who are drug nihilists (and yet some of the worst mixtures are often used by them), and those who believe in the pharmacologic and chemical action of drugs and yet ridicule the art of good prescription-writing as beneath their dignity. Such men often write the most uncouth prescriptions and the most absurd combinations in order to get the desired action of one drug."

A number of prescriptions written by physicians of wide reputation are discussed. Regarding one designed to reduce acidity in gastric ulcers and containing infusion of rhubarb, sodium bicarbonate and peppermint oil it is said:

1. An infusion of rhubarb root is too disagreeable to administer to anyone. In the next place, it could have no action whatsoever on gastric ulcer or gastric acidity. Its reaction is that of a bitter laxative.

2. Theoretically, oil of peppermint should not be administered in gastric ulcer, as the stimulation of a carminative can do nothing but cause the outpouring of more gastric juice, even if menthol directly applied to the ulcer might, in some instances, help it to heal.

3. The only object of this prescription, then, is the bicarbonate of soda, which would act chemically to temporarily diminish the gastric acidity, and might therefore stop pain.

4. It is utterly absurd to order such a prescription administered twice daily without specifying the time in relation to meals, to pain, or to any action of the bowels which might occur from the rhubarb.

Regarding a prescription ascribed to Ewald and containing calcined magnesia, sodium bicarbonate, potassium bicarbonate, powdered

rhubarb and milk sugar, to be given every half hour, it is said:

1. There is no difference of any importance in the action of sodium carbonate and potassium carbonate; therefore there is no object in using both.

2. Sodium carbonate is more or less irritant; sodium bicarbonate is hardly irritant at all. There is therefore no reason for using sodium carbonate in place of sodium bicarbonate.

3. Powdered rhubarb root is intensely disagreeable to take, and cannot help in reducing the acidity of gastric juice; in fact, any bitter will increase the outpouring of gastric juice. If a laxative is desired, it certainly should not be administered in this manner.

4. Any sugar, even sugar of milk, is better not given to a patient in whom one is attempting to reduce hyperacidity.

5. The only satisfactory action from this prescription must come from the heavy magnesia, but even its gentle alkaline action would be overcome by the combination in which it finds itself.

6. Half a teaspoonful of a powder containing rhubarb, administered every hour without a definite limit, certainly seems bad therapy.

Regarding a prescription of Elsner designed to reduce hyperacidity and to relieve pyloric spasm, containing belladonna extract, sodium bicarbonate and magnesium phosphate, it is suggested that the latter is worthless, that the first should be given by itself if the action of belladonna is wanted, and that the bicarbonate of sodium is the only valuable constituent.

Similarly prescriptions credited to Trouseau and to Cohnheim are criticised and an appeal is made that physicians should think when they write their prescriptions.

WORTHLESS COUGH SYRUPS.

From the therapeutic department of the *Journal* (Dec. 30, 1911, p. 2139) the following discussion of an old shot-gun prescription which is in our Pharmacopoeia, namely, *Mistura Glycyrrhizae Composita*: Brown Mixture, is taken:

Let us hope that this preparation will not be official in the ninth revision of the United States Pharmacopoeia. Let this preparation be forgotten and go into innocuous desuetude. Why? Because it is an absurd mixture, and it is a shame to put it into a perfectly good stomach. Even if a patient happens to have a cough, why should his stomach be upset with any nasty, sweetish cough mixture?

What does brown mixture contain? *Mistura glycyrrhizae composita*, U. S. P., contains:

Pure extract of glycyrrhiza.....	3 gm.
Syrup (sugar)	5 cc.
Acacia, granulated	3 gm.
Camphorated tincture of opium ..	12 cc.
Powdered opium	0.4 gm.
Benzoic acid	0.4 gm.
Camphor	0.4 gm.
Oil of anise	0.4 c.c.
Glycerin	4 c.c.
Diluted alcohol	.95 c.c.
Wine of antimony	6 c.c.
Spirit of nitrous ether	3 c.c.
Water, sufficient quantity to make	100 c.c.

It seems a shame to continue to give bad-tasting, sugary preparations in the attempt to combine prescriptions for coughs. There is practically no activity whatsoever, except to upset the stomach, in any of the cough syrups. If ammonium chlorid is selected as the expectorant desired, and there is none better, let it be administered in a sour preparation, or given in simple water, without or with a flavor, as peppermint or wintergreen. A disagreeable after-taste may be quickly eliminated by a taste of orange or lemon, as the patient desires; or the ammonium chlorid watery solution may be administered in an effervescent water.

CHANCE FOR A KENTUCKY DOCTOR.

The American Red Cross desires again to invite attention to the exhibition in connection with the Ninth International Red Cross Conference, which will be held in Washington, D. C., from May 7 to 17, 1912.

The exhibition will be divided into two sections, which will be styled Marie Feodorovna and General. The former is a prize competition, with prizes aggregating 18,000 rubles, or approximately \$9,000, divided into nine prizes, one of 6,000 rubles, approximately \$3,000; two of 3,000 rubles each, and six of 1,000 rubles each.

The subjects of this competition are as follows:

1. A scheme for the removal of wounded from the battle-field with the minimum number of stretcher bearers.
2. Portable (surgeons') washstands, for use in the field.
3. The best method of packing dressings for use at first aid and dressing stations.
4. Wheeled stretchers.
5. Transport of stretchers on mule back.
6. Easily folding portable stretchers.
7. Transport of the wounded between warships and hospital ships, and the coast.
8. The best method of heating railway cars by a system independent of steam from the locomotive.
9. The best model of portable Roentgen

apparatus, permitting utilization of X-rays on the battlefield and at first aid stations.

The maximum prize will be awarded to the best exhibit, irrespective of the subject, and so on.

The General Exhibit is again divided into two parts; the first will be an exhibition by the various Red Cross Associations of the world. The second will be devoted to exhibits by individuals or business houses of any articles having to do with the amelioration of the sufferings of sick and wounded in war, which are not covered by the Marie Feodorovna Prize Competition for the year. While the American Red Cross will be glad to have any articles pertaining to medical and surgical practice in the field, it is especially anxious to secure a full exhibit relating to preventive measures in campaign. Such articles will be classified as follows:

1. Apparatus for furnishing good water in the field.
2. Field apparatus for the disposal of wastes.
3. Shelter such as portable huts, tents and the like, for hospital purposes.
4. Transport apparatus (to prevent the suffering of sick and wounded) exclusive of such apparatus as specified for the Marie Feodorovna Prize Competition.

As with the Marie Feodorovna Prize Competition, for this country only articles having the approval of the Central Committee of the American Red Cross will be accepted.

Diplomas will be awarded for exhibits in this section of the exhibition as approved and recommended by the jury.

Further information may be obtained from the Chairman, Exhibition Committee, American Red Cross, Washington, D. C.

It is perhaps to apparatus having to do with prevention of disease in armies that the energies of Americans have been specially directed since the Spanish-American War. Therefore, the last mentioned section of the Exhibition should make an appeal to them.

NATURAL VERSUS SYNTHETIC SODIUM SALICYLATE.

Through its committee on therapeutic research, the Council on Pharmacy and Chemistry has undertaken to settle once for all the question whether or not sodium salicylate made from oil of birch or oil of wintergreen is better than sodium salicylate which is made from salicylic acid derived synthetically from phenol. While on the face of it, pure sodium salicylate, i. e., that complying with the standards laid down in the Pharmacopoeia should have the same properties, no matter how made, certain proprietary houses lay great stress on the superiority of the kind

which they sell and which they claim to be made from natural oils. Inasmuch as many physicians have accepted these claims of superiority and in their prescriptions specify the "natural product" which costs more than ten times as much as the best "synthetic," it is most opportune that the Council should have taken the matter up. Under the direction of Torald Sollman, a member of the Council and professor of pharmacology at Western Reserve University Medical School, it is proposed to study the question chemically, pharmacologically and clinically. While the chemical work is still under way in the association laboratory and the clinical tests are being made in a large number of hospitals, the pharmacological investigation by Prof. Waddell, University of Virginia, has been completed. (*Archives Internal Medicine*, December 15, 1911, p. 784.)

The report of Prof. Waddell is preceded by a general introduction by Dr. Sollmann, in which is shown the insufficiency of the evidence on which the champions of the "natural" sodium salicylate have based their claims. Sollman brings out clearly on what slim, shadowy evidence an interested party will base the most positive statements and how, not being familiar with the nature of the evidence, physicians have accepted, in the past, mere whims or fancies as proven facts to the detriment of therapeutics.

The result of Dr. Waddell may be summed up in a few words: All the brands of sodium salicylate, whether "natural" or "synthetic" had identical effects on cats, rats and rabbits. It is hard to imagine that human beings will be differently affected.

SCIENTIFIC EDITORIALS.

AUTOINTOXICATION.

There is no term employed in medicine that is so frequently used and misused as auto-intoxication. It is in the words of the Psalmist "an ever present help in time of trouble." But like malaria it has been used to describe many conditions that have nothing to do with intoxication at all. One bad result has grown out of this indefiniteness of statement and that is that the use of such terms leads to looseness of thinking and is far removed from that scientific spirit of exact knowledge that we should all strive for. Again there has been great advance made in the last few years in our knowledge of some of the illy understood morbid processes and we can now assign many of these to quite definite and well understood processes. In view of the complexity and magnitude of the subject one may be excused if only certain phases of this broad field will be alluded to in this brief

consideration of the subject. We shall limit ourselves therefore to the consideration of the intoxications which are of gastro-intestinal origin. With the admirable monograph of Prof. A. E. Taylor upon this subject in *Modern Medicine* one must in the main necessarily agree. There are, however, certain hypotheses of still more recent date which show the advance in this short time.

There are five possible sources of intoxication from the intestinal canal. These are, according to Taylor: Digestive fluids and secretions; normal products of digestion; abnormal products of digestion; substance formed normally from food by bacteria within the alimentary canal; and abnormal products of bacterial disintegration.

The resorption and intoxication from the digestive juices may be ignored for the ferments are colloids which are not readily absorbed. The salivary ferments are digested by the pepsin which in turn is destroyed by the trypsin and it with the other intestinal ferments is hydrolysed and destroyed by the bacteria in the intestines.

The products of normal digestion when introduced into the blood in an abnormal way are toxic. We can hardly affirm that in the normal gut they would ever produce an intoxication. Albumoses and peptones when injected hypodermically may cause fever associated with other phenomena. One might question whether in abnormal states of the intestinal mucosa there may not be a more direct absorption of these products without having undergone those changes in the proteins which are effected by the mucous cells in the mucosa.

The products of an abnormal digestion might well be considered as potential causes of intoxication. Taylor thinks, however, that there is no evidence to support the above hypothesis. Let us consider for a few minutes the most recent accepted theory of the digestion of proteids. It seems to be agreed at present that the albumin molecule is made up of a number of simpler molecular radicals most of which belong to the amido-acids. These radicals are by no means so simple that they can be readily formed in the chemical laboratory. When the protein reaches the stomach it is fractioned into these simpler radicals. When these reach the intestine the trypsin and other ferments fractionate them still further and into simpler molecules. These are now picked up by the mucous cells of the intestinal villus and are recombined into the serum albumin and globulin which are characteristic and peculiar to the animal. There are possibilities which will be alluded to here but will be discussed more fully later. Some of these fractions are known to be non-toxic. Others are as yet undetermined. It

is agreed that a normal mucous membrane can handle these products without difficulty but it is not so settled that an abnormal mucosa will be so able to distoxicate or prevent the absorption of these poisonous substances. To broaden the scope of our discussion let us take up the two remaining sections of our subject—the products which are formed by bacteria out of normal food and out of abnormal food. Here is the real crux.

Bacteria produce out of the ordinary food certain well known substances which are handled by the system without any injury as a rule. Besides this the intestinal mucosa seems to have a distinct factor of safety as it may be called, in that it and the system in general can take care of more than a minimum of toxic material. It is claimed that the decomposition products formed in the intestine by the bacteria from normal foods are not toxic. It is also claimed that the putrefaction of food rarely causes any auto-intoxication because most of the products formed are taken care of by the body. It is said to take ten days to form ptomaines and therefore it is impossible to have ptomaine poisoning unless the protein had undergone putrefactive changes before it was taken as a food. This does not take into account the clinical fact that food remains in the intestinal canal some times longer than ten days. We have all seen cases of the passage of food remnants which had been in the bowel for much longer than ten days, and therefore, it is not inconceivable that ptomaine poisoning might arise from some of these retention products.

The contention of Taylor that intoxication from the bowel is a fallacy except when the food has spoiled before being ingested is open to these several criticisms. It is the experience of every one who practices upon children that they are particularly liable to sudden attacks of a very violent nature following a change of food. After the occurrence of diarrhoea from any cause the baby will be put upon a protein free or low diet. After some days of this low diet the attempt is often made to return to milk in very weak dilution. At once there is an alarming outbreak of severe symptoms and sometimes the life of the child is lost. In such cases we can not understand how such severe toxemia could have arisen with so little to explain it. There is no change in the flora of the bowel. The milk itself is pure, fresh and free from any bacterial infection and yet the case flares up like a cyclone with death as the result. There are several probabilities which may be suggested. The intestinal mucosa denuded of its natural protecting layer of cells may absorb into the capillaries toxic material which would normally be kept out by the normal cellular activities. The protective layer

being gone the toxins go direct to the liver whose distoxiating powers have been abrogated by the original disease. If one will examine and outline carefully the liver in every case of intestinal trouble he will be surprised how often he will find that organ enlarged and evidencing the fact that it has had much work thrown upon it in the way of taking care of the toxins which are being absorbed from the intestinal lumen. Post-mortem we shall find that the hepatic cells have been worsted in the strife and have undergone a fatty degeneration. The size of the liver helps to measure the amount of toxemia which is being carried to it. A very little additional work put upon it may at the critical moment prove the proverbial straw. Unfortunately Taylor has shown that the urine which has been relied upon so much to give us intelligence in these cases by the indian and other tests of the formation of the tryptophane end products, is unreliable. He says: "There is no clinical parallelism between symptoms and the conjugated sulphates in the urine, either in degree or in the onset and disappearance. What is all along actually assumed is that other substances, poisons, are produced by the putrefaction; and as the degree of putrefaction may be often approximately measured by the aromatic substances, the degree of the hypothetical poisoning is also so measured." In other words he does not believe such tests to be of any value in determining the toxemia.

A second possibility must be threshed out. The bacteria undoubtedly destroy the protein molecule with the formation of a number of comparatively simple chemical end-products which are not toxic or the cause of intoxication. But the protein molecule is a very complex molecule and it is not inconceivable that the cleavage of that molecule may result one time in the simple non-toxic entities and yet by another cleavage create highly complex compounds of an alkaloidal toxicity. Our knowledge of these chemical changes and reactions is as yet too chaotic to enable us to state too dogmatically our opinions.

With the advent of the serum therapy and the frequent use of horse serum for the relief not only of diphtheria but for many other diseases and even for their prevention we are hearing more and more of serum disease and anaphylaxis. When one has an opportunity to see a well defined case of anaphylaxis his respect for the potential dangers of serum will be immeasurably increased and he will not be anxious to resort to such potent agents when they are not necessary. Caille in the last issue of the *Pediatrics* sounds a warning note which has been expressed for some time in the foreign literature against the indis-

criminate use of immunizing doses of even such an accepted agent as diphtheria antitoxin. The pendulum has begun to swing back somewhat. As Dr. Allen has so patently remarked: "An agent which is capable of great good is also capable of harm." Now the explanation of anaphylaxis as at present accepted is that the cleavage of the protein molecule proceeding in an abnormal direction so to speak has produced a poisonous product which may even be fatal. Pisek has recently suggested that some of the phenomena of difficult digestion in bottle babies are in the nature of anaphylactic phenomena.

One may propound the following theories as acceptable if not accepted. The possibilities of intoxication from the intestinal tract are not fully known and understood. Bacterial products which are not as yet determined may be produced in the gut and cause symptoms by their absorption. Abnormal cleavage of the protein may be caused by pathogenic and by so-called normal bacteria whose potential capacities are by no means fully determined. Toxic cleavage may arise not only from the bacteria but from the mal action of the digestive ferments.

PHILIP F. BARBOUR.

THE VALUE OF BLOOD ANALYSIS IN OTOTOLOGY.

Favored by the vast material of the Vienna Clinics and the concentration of the work in the Allemine Krankenhaus, Dr. E. Urbantschitsch has been able to study the condition of the blood in quite a number of ear cases, the result of which he has recently published in the *Monatschrift für Ohrenheilkunde*.

He calls attention to the error of most hematological examinations in otology of studying only the relative proportion of the red cells and the leucocytes and expresses the belief that the real worth of the blood analysis lies in the study of the relative proportion of the different leucocytes amongst themselves.

Urbantschitsch examined the blood in 75 cases. He took the specimens from the lobe of the ear of the unaffected side, and used the blood counting apparatus of Zeiss. The dry specimens were stained according to the method of Leishman. The specimens were all taken in the morning to avoid the leucocytosis of digestion. He also avoided as much as possible the withdrawal of blood during high fever and during coincident or intercurrent diseases.

A brief extract of the exhaustive report of Urbantschitsch will suffice to show the class of cases in which hematanalysis is of value.

In ten cases of *acute purulent otitis media*

and *acute mastoiditis* in which the blood was examined moderate leucocytosis (9,000 to 11,600 L) was found in nine cases and a high degree of leucocytosis in one case (15,000 L.) The high degree in this case was accounted for in the existence of high temperature of the patient at the time the blood was taken. The relative proportion of neutrophile and eosinophile leucocytes remained undisturbed in all of the cases but two and in these the disturbed relations was due to other causes (abscess of the soft parts.)

In ten cases of *chronic purulent otitis without cholesteatoma* but two showed, in addition to leucocytosis, an increase in neutrophile (polynuclear) and decrease in eosinophile cells indicative of intracranial complications. However in the one the disturbed relations were found to be due to an intercurrent abscess in the ear canal and the other to the close proximity of the lateral sinus to the abscess. Several of the cases with normal blood cell relations showed alarming symptoms as nausea, dizziness, headache, etc., which subsequently subsided, thereby indicating the absence of intracranial complication.

In three cases of *chronic purulent otitis with cholesteatoma* one case showed moderate leucocytosis with increase in neutrophile and decrease in eosinophile cells significant of intracranial complication which, however, did not develop, showing that disturbed blood cell relations is not an infallible diagnostic sign.

In thirteen cases of *middle ear inflammation without perforation of the drum* those resulting in non-purulent bone destruction showed normal blood relations while all of the purulent cases showed leucocytosis with relative increase in neutrophile and decrease in eosinophile cells. Two of these cases were of special interest, one because the mastoid was opened and revealed pus entirely on the evidence of the blood count after local conditions and subjective symptoms of mastoid disease had about disappeared; the other, just the reverse of his case, where with persistence of subjective symptoms of mastoid disease normal blood relations decided against an operation and the case finally returned to normal.

In six cases of *extradural and perisinous* subsequent to the radical mastoid operation, the blood count showed normal relations.

In six cases of *extradural and perisinous abscess* the cases of developed perisinous abscess were associated with marked leucocytosis and relative increase of neutrophile and decrease in eosinophile cells and in the cases with pus away from the sinus between the dura and bone the blood analysis showed only a slight leucocytosis with neutrophile cells in normal proportions but eosinophile cells completely absent.

In nineteen cases of *sinus thrombosis*, *pyemia* and *sepsis* positive leucocytosis, though not always of a high degree, was present in every case as was an increase in neutrophile and decrease in eosinophile cells.

In five cases of *meningitis* the four purulent cases showed leucocytosis of high degree (20,000 to 40,000 L) and marked increase in neutrophile and absence of eosinophile cells. The single case of serous meningitis showed normal relations of blood cells.

In three cases of *brain abscess* a high degree of leucocytosis was present. In the two fatal cases an entire absence of eosinophile cells was noted while the case which recovered showed only a reduction of these cells.

Based upon the observation of these 75 cases Urbantschitsch comes to the following conclusions: That a diagnosis in ear diseases can not be made by the blood count alone but that hematanalysis is of considerable value in conjunction with clinical symptoms;

That the presence of leucocytosis in itself is not a positive sign of bone suppuration but when associated with disturbed relations of the neutrophile (polynuclear leucocyte) and eosinophile cells it is of great diagnostic and prognostic importance; that the uncomplicated cases of acute and chronic middle ear suppurations are associated with only slight increase or normal proportion of leucocytes with normal relations of the neutrophile and eosinophile cells but that coincident abscesses of the soft parts can bring about blood changes simulating those found in intracranial complications;.

That the blood count is of undoubted diagnostic value in those cases of pus in the mastoid in the absence of otorrhoea. A slight leucocytosis and the same disturbed relations between the neutrophile and eosinophile cells as in intracranial complications is always present and in the absence of other conditions to bring on this blood change is sufficient evidence to warrant a mastoid operation;

That the hematanalysis is of little or no diagnostic value in diseases of the labyrinth;

That leucocytosis with marked increase in neutrophile and marked diminution or entire disappearance of eosinophile cells is uniformly found when intracranial complications exist. Although the changes are as a rule most pronounced in purulent meningitis, the blood analysis merely indicates the presence of intracranial pus but can not be relied upon to differentiate between meningitis, sinus thrombosis and brain abscess;

That marked increase of neutrophile and absence of eosinophile cells with leucocytosis of any degree can always be looked upon as a bad prognostic sign.

ADOLPH O. PFINGST.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form facts about the composition, quality and value of medicines. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A. Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and the Chemical Laboratory.*

TIZ

"Tiz" is a widely advertised toilet article in regard to which The Journal A. M. A., has had many inquiries. It is produced by Walter Luther Dodge & Co., Chicago, and is called a "new, scientific, medical, toilet tablet." Among other claims are: "It is different from anything ever before sold." "Small shoes can be worn by using Tiz." "Guaranteed to cure corns, callosities, bunions, frost bites, chilblains, ingrowing toe nails, tired, aching, swollen, bad-smelling feet." "Draws out all poisonous exudations which bring on soreness of the feet and is the only remedy that does; cleans out every pore, and glorifies the feet—your feet." In response to the inquiries, The Journal A. M. A., December 2, published the results of the examination of the product in the chemical laboratory of the American Medical Association. From this examination it is believed that a tablet having properties like "Tiz" would have the following composition:

Potassium aluminum sulphate (alum)	60 per cent.
Tannic acid	10 per cent.
Salicylic acid	5 per cent.
Talcum (talc)	5 per cent.
Starch	20 per cent.

For years physicians have prescribed these astringent drugs thus advertised by quacks as a cure-all, according to the time-worn methods of quackery. There is nothing new in the treatment which is only what any physician might devise. Like most nostrums, "Tiz" is exploited with disregard for truth and is simply an attempt to exploit the public.

LIQUID SULPHUR—SULPHUME.

As an instance of the revival of an ancient fake, the venerable Vleminkx' solution, The Journal A. M. A., December 2, publishes an expose of Sulphume, concerning which a number of inquiries had been received. A package of this product recently purchased bears the following legend: "Sulphume for the skin and blood. The

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

contents of this bottle makes 10 strong sulphur baths. Dose—Internally: Four to six drops of Sulphume in one-half tumbler of water 3 times daily, one-half hour after meals. Price \$1.00. Sulphume Company, Boston, U. S. A." Accompanying the bottle is a booklet entitled "Sulphur and Its Benefits to Health," in which Sulphume is lauded for its value in treating all sorts of skin diseases, catarrh, corns, bunions, diabetes, diphtheria, female weakness, fevers, hemorrhoids, rheumatism, prostatitis, rickets, etc. Details of the chemical analysis are given. The preparation is essentially an aqueous solution of calcium polysulphoid and thiosulphate, such as is obtained when a mixture of lime and sulphur is boiled in water. A solution of this kind is described in the National Formulary under the title of Liquid Calcis Sulphurate, 32 ounces of which can be made at a cost of about 8 cents. The Journal says that, while some physicians still attribute some value to sulphur as an alterative and general antiseptic and as a remedy in skin disorders, it has come into rather general disuse by the regular profession at the present time. The public, however, is still taken in by bad smelling drugs.

RADIUM TEAS.

A reader of The Journal, (Dec. 23, 1911, p. 2098) asks whether the newspaper accounts of radium teas, at which patients are exposed to radium emanation for a number of hours while they play cards or read and take tea, which is said to be a fad in Paris, is "pure guff" or an "actual scientific process." The Journal states that this form of radium treatment is taken seriously abroad and we who live in the land of the gullible may soon expect to have radium tea rooms, radium whist clubs, and what not.

OFFICIAL ANNOUNCEMENTS

STATE BOARD INVESTIGATION.

The Committee on Kentucky Statutes is investigating the State Board of Health at the instance of Mr. Herrington of Madison county. The Board and the State Medical Association will welcome the investigation as it will make the whole people better aware of the character and extent of the work being done by both. The following is the statement of Dr. J. N. McCormack:

Mr. Chairman and Gentlemen of the Committee:

In order to economize in time, with your permission, I present to you the minutes of the State Board of Health, showing its operations in detail from its creation over a generation ago to the last meeting held in this hotel on the 10th of the present month: the Treasurer's books and numbered vouchers for

each item, accounting for every dollar appropriated and expended by the Board since I became its secretary, October 1, 1883, and containing for each year a report of the committee appointed to audit the books and vouchers, certifying to their correctness at the bottom of each annual statement. These minutes and financial transactions have been published for each biennial period and widely distributed.

When the enlarged appropriation became effective January 1, 1911, after discussion with the Board, and conference with the present and former State Examiners, it was decided that the method of keeping the financial records could be improved and extended, and I present to you a full detailed, numbered statement of each expenditure under the appropriation of \$30,000, with a voucher-check, receipt and itemized account corresponding to each entry, and indicating the department for which the expense was incurred, duplicates of these voucher-checks having been filed with the Auditor of Public Accounts, as required by law. Attached to this financial statement will be found the report of the Potter-Matlock Trust Company, employed to audit the books and vouchers, and that of the Auditing Committee of the Board appointed for the same purpose. All of these itemized statements and other matters will be embraced in the forthcoming volume of transactions and become an open book to every citizen.

In this connection it may be of interest for you to know that the Board was created upon the recommendation of Governor McCreary in 1878 to meet the emergency of an epidemic of yellow fever then raging in the south, and that, before the appropriation became available, with funds raised upon the personal credit of its members, who served then, as now, without compensation, it was in the field fighting to protect the health and lives of our people. For the first twenty-two years the total appropriation for the work was \$2,500, after which, until last year, it was \$5,000. During all these years the work of the Board has ranked well up with those of other states having five and ten times the funds. This was only possible because the members of this Board and 695 members of county and city boards of health served without compensation except for their executive officer, and because I furnished the Board an office in my residence, with heat, light and janitor free of cost, as our hospital is now doing for one of the laboratories, and for years my wife and son, and in times of emergency, every servant in the household, assisted in the clerical and stenographic work and in getting out the enormous mail, without any or at only a nominal cost. At different times when my son was away at college, Walker D. Hines, now at the head of the Sante Fe system, and

McKenzie Moss, now Circuit Judge in my district, took his place in the morning and evening when not in school for ten dollars a month. For all these years my son and I, long before he was a doctor and since, were on the border where pestilence threatened from the south, and in the counties in every section during smallpox and other epidemics, our overalls were covered with scabs and pus while we helped to carry the sick to the improvised hospitals and to bury the dead, a service which most of you would not render for all the revenues of Kentucky. More unpleasant than all of these things, and because no one else would do it, I haunted these legislative halls year after year, often classed as a lobbyist by those who did not know any better, but most nobly supported by my profession of every school of practice, as I am now, begging that authority be given my Board and profession to protect the people from pestilence and impure food, drugs and quackery, and so successfully that the laws on most of these subjects, written by me, are used as models in other states.

At the outset, the State Board of Health was a purely political body, pull having more weight than fitness, and, while excellent men personally, many of them had little training, and often could not afford the time for its duties. One Governor went so far as to exact a pledge of each appointee that he would vote to put the health and lives of the people of Kentucky in the hands of one of his political friends, and only failed because this most worthy physician declined to accept the position when he knew what would be required of him. The county boards were then appointed by the fiscal courts and were little more than farces. All this became such a recognized evil that representatives of all schools of practice agreed upon and secured the passage of the present law, which put the selection of members upon a scientific basis, with the result that the men now composing the Board will bear favorable comparison with the Court of Appeals or any other body of men in the State. On account of his wisdom in public affairs, and the interest he has always taken in health matters, the present Governor could be safely trusted to make nominations on the Board without restrictions, but this was intended and was agreed upon as a permanent provision, because sad experience has taught us that the average governor was no better qualified to select members of the Board than the average doctor would be to select judges of the highest courts, and that it would be just as reasonable to put such authority in his hands. The same principle applied to the appointment of county boards of health by the fiscal courts, and this will be realized when the people come to know that

health and life and the officials who protect them are more important than property interests and the courts which look after them. The county boards are now selected upon merit alone. They serve without compensation, and yet the spirit of the profession is such that there has never been any trouble in getting the best men to serve. I hand you the lists of these boards for thirty years that you may study them and ascertain if they are men who could be dominated by any man, and that such an insinuation is a reflection only upon those who inspired it. To return to this vicious system, discarded because it was vicious, and put us back in the pool of politics would be a step backward which would and ought to be condemned by all right thinking people who have no personal friend or end to serve, and I have no fear that it will ever be done.

When the \$30,000 appropriation was secured it was at once decided to try to do twice or thrice that amount of work with it. With this end in view competitive bids were secured on all laboratory and other equipment and supplies, much of the scientific apparatus coming from abroad duty free, often with a saving of 50 per cent. or more. The heads of departments and employees were put upon minimum salaries and stimulated to do the best that was in them by promise of better compensation as soon as all the cost of equipment was paid. All of them have made good, and the bacteriological department has saved more to the people on diphtheria and rabie serums alone than its entire cost for the year, and without adverse legislation the good to come to the homes of our people from these activities is beyond computation. We have the best equipped laboratories in Kentucky for their purposes and scope, and I ask you to visit and inspect them, as the health committees of both houses have been asked to do.

A few men have tried to dominate Kentuckians, but no one has ever succeeded. I hold no office in the State Medical Association, and have not for twenty-eight years when I was its President, and my opinions have weight with my profession only because of what I have done for it. This hand has written every health and medical law on our statute books, our health reports, now used as text books in our normal and hundreds of district and high schools, and almost every health circular and leaflet. I led the organization movement in every county, pleading for and securing harmony where there had been discord, and bringing together all schools of practice. Completing the organization of my own State, nine years ago, after consultation with the Board, and upon its advice that the Board's prestige and my usefulness would be greatly increased thereby, I accepted the position of

Chairman of the Committee on Organization and health lecturer of the American Medical Association for the United States, and, in that capacity, have inspected and spoken upon health conditions in ever principal city and county in this country. In doing this my engagements were such that I only missed two meetings of the Board and could always be here should an epidemic occur. Upon the completion of the laboratories, the possibilities for good to our own people so impressed me that I resigned this position, with its salary of \$6,000, over the protest of the National Association, to devote the remainder of my active life to the improvement of health conditions in my native State, upon the same salary paid my stenographer, and which I have never asked to be increased in all these thirty years. Is it surprising that the profession are my friends, and that they consider an attack upon me as being made upon themselves? But it is charged that the profession is not for me. In order to put this to the test I now propose that if any state association, homeopathic, eclectic or osteopathic, or any county society, including Mr. Herrington's, and there is no better one, will ask it, I will join in the request for the referendum vote provided on all matters by our Constitution, and will cheerfully resign if 90 per cent. of all the doctors do not support my policies and work.

In conclusion, nearly thirty years ago, by a unanimous vote, I was made the executive officer of this Board, and this has been done at regular intervals since until two weeks ago, upon motion of the homeopathic member, seconded by his osteopathic colleague, I was again elected unanimously for a term of four years. In all these years my life has been an open book both to the profession and people, and I have done my duty to every interest as God gave me the capacity to see it. This is the first, and, with the fair and impartial hearing I know you will give, I expect to make it the last, time any man has ever questioned my motives, my capacity or my integrity. My respect for this Committee, my profession and for myself has kept me from trying this issue in the public press, as my traducers have attempted to do. Most of you are strangers to me, and, since the day this question assumed a personal phase, I have spoken to no one of you on the subject, greatly interested as I am in other bills before you, and have asked no assistance from any county board of health or physician, or written or inspired a letter to one of them. I do not need the pittance of a salary, ask no man's favor and would despise myself if I accepted any man's sympathy. I only court the full, fair investigation which I know you will give me, and then—justice.

THE PHYSICIAN'S DUTY AS AN EDUCATOR IN PREVENTIVE MEDICINE.*

By J. W. ELLIS, Masonville.

When I made my debut into the medical profession, way back in the last century, I found physicians everywhere, studying symptoms of disease and their treatment, the reason for which was that the exact cause of but few diseases was known and the practice of medicine was but little more than empiricism. Then when the physician had visited his patient and prescribed for his symptoms, he thought he had done his whole duty, and perhaps he had under the then existing state of medical knowledge, for preventive medicine was unknown.

It was reserved for the last quarter of the nineteenth century to produce the immortal Robert Koch, who in the autumn of 1882, announced to the medical profession his discovery of the tubercle bacillus, as the exact cause of tuberculosis.

He demonstrated the fact that this particular microorganism was always present in tuberculosis, and that it was the exact cause of the terrible disease. With this startling and supremely important discovery, a new era dawned upon the medical world and medicine had for the first time become almost an exact science.

Immediately bacteriology sprang into existence, and physicians everywhere were busy trying to discover the exact cause of every disease with which humanity is affected, with the result that the cause of nearly every disease is known and preventative medicine is born.

The relation between the physician and the laity was at once changed. Theretofore the laity had been consulting the physician in regard to his symptoms and their management, but to-day he is asking his physician the far more important question, how he can escape disease.

In consequence of the marvelous advances in medical science, and the accumulation of medical knowledge, physicians are to-day able to point out the danger signals, and recognizing the fact that they are the custodians of the health and lives of the people, are cheerfully and courageously betaking themselves to the task of preventive medicine.

The public heretofore has received its teaching in regard to disease and its management from patent medicine fakirs, who fill the pub-

*Read before the Kentucky State Medical Association, Paducah.

lie press, with misleading statements, about the virtues of their vile, habit-producing nostrums. It is no wonder the physician finds bottles and boxes of this stuff in nearly every house he enters, when he reflects, that the public press of the land, the great educators of the people, is the medium through which these vampires reach the public.

It is the duty of the physician to remonstrate with the public press, both secular and religious, and to point out to them the blighting effects of this false teaching upon the lives and happiness of mankind, to which they are unwittingly lending their great influence and alone making it possible for them to victimize the people.

When the medical profession succeeded in getting the Pure Food and Drugs law enacted, much, they thought, had been accomplished toward protecting the public from the nefarious practices of food dopers and nostrum venders.

In a test case, the supreme court has decided that the measure falls far short of what its originators intended, and the physicians should suggest such amendments as would make the bill effective.

Already the great work of physicians in preventative medicine is beginning to be felt and appreciated by the laity. Just the other day, President Taft sent a message to Congress, urging the strengthening of the Pure Food and Drugs Law, and banishing fraudulent nostrums, holding forth false promises of cure in a multitude of diseases.

The message is a sequel of the recent decision of the Supreme Court above referred to, which ruled that a manufacturer could legally label a nostrum as a cure for disease, although he knew it to be worthless in the treatment of that disease. Physicians should insist that Congress pass further legislation providing that no misbranding or misleading statements, whatsoever, may be placed on the labels.

Our own Mr. Sherley, of Louisville, has already introduced a bill bearing on the subject, and early action in the matter is earnestly desired. If the people are being taught daily by the bureau of agriculture the great importance of the conservation of our natural resources, how much more important is it that they should be taught the importance of the conservation of human life, and nowhere else could this be done more effectually than by a bureau of health with a medical man in the President's Cabinet, a measure physicians are now urging and should continue to urge until it becomes a law. This department, if established, would at once become an educational center and the public, in search of health would not be left to be

misled and misguided and deceived by patent medicine advertisers.

This altruism on the part of physicians is regarded by some as an effort to establish a doctor's trust, and on the very threshold of their undertaking are met with organized resistance. A few pious, though misguided people have allied themselves with quacks, irregulars and the great patent medicine interests and organized a so-called "League for Medical Freedom," an organization, the sole object of which is to perpetuate the power of these patent medicine concerns and leave unmolested these charlatans, whose sole end and aim is to rob the afflicted, and who are to-day a menace to the happiness and well being of all mankind. These are the people who are making the unholy fight on Dr. Wiley and demanding his removal from the position of Government chemist, which he now holds. Dr. Wiley's great sin is his ability to detect fraud, and his honesty to announce it to the world. Physicians everywhere should stand by him for he is doing a work that will benefit universal humanity.

It is a well known fact that many diseases have been spread by infected hands. Simon Flexner has gone so far as to declare that perhaps "the chief compelling phenomenon" is that of microbe carriers. They have been found to disseminate typhoid fever, dysentery, cholera, influenza, spinal meningitis, and many others diseases.

Dairy workers, cooks, and bakers, with unwashed and infected hands are great sources of danger to the public and should be instructed to that effect and that they should no longer remain in the class of the great unwashed. It is the duty of physicians in their fight for preventative medicine to insist on the abolition of all drinking cups at public places, on trains, in hotels and wherever people congregate, and the substitution of separate paper drinking cups, strict enforcement of the spitting law, absolute enforcement of the law requiring all physicians to report all transmissible diseases, and the thorough disinfection of all premises occupied by such subjects. Typhoid fever should be a reportable disease, and the people taught to boil the drinking water, and all the utensils used by the patient kept from other members of the family. The milk supply of a family afflicted by the disease should be examined by the health bureau, all dairies and milk farms should be inspected and the cows carefully examined for tuberculosis.

As all reform must come from physicians along health lines, I think they should by public addresses and short newspaper articles instruct the laity that when one is physically injured, one should not wrap the wounded part in old dirty rags, but hasten to the

nearest physician and have an antiseptic dressing applied, thereby eliminating the danger of infection, instructions how to prevent other surgical conditions should be given—the absolute necessity of keeping the bowels open to prevent the development of hemorrhoids, to overcome the tendency toward appendicitis, the formation of gall-stones, colitis, etc.

With these duties and many other similar well performed, the physicians' duties to society and the public generally are hardly begun. The importance of these duties pale into insignificance when compared with solving the great problem of saving society from degeneracy and premature decay. To-day our prisons and charitable institutions are overflowing and why? Plainly because there has been no attention paid to marriage laws, and the prevention of the multiplication of the idiot, the imbecile, and the common criminal. The problem of the proper management of this, now very numerous class of people demands our serious attention and prompt action, if we are to save society and the state from a steady lowering of moral standards and consequent degradation and national disaster. The burning question at once arises, what can and should be done in the premises by the medical profession.

Evidently the state cannot take these unfortunate people and care for them. We have got to lose sight of the individual idiot, degenerate, and common criminal, and adopt measures that will prevent the production of new generations of these unfortunates. J. Ewing Mass, of Jefferson Medical College, suggests sterilization as the proper thing, and I fully concur with him and regard that by this means, and this only, can this class of undesirable citizens be properly cared for, and saved from themselves.

Doubtless physicians in the discharge of their duty along this line would be met with the argument, that these people have personal rights, that should be respected, but I deny that any one has the right to produce a class of people that would not only become wards of the state, but whose idiocy, imbecility and criminality would have a deadening effect upon all society.

It has been my observation that these degenerates are the most prolific people on earth and when mated produce the biggest families to be found, and as "nothing from nothing comes," this numerous progeny goes to swell the ranks of that rapidly increasing class of citizens that are already a menace to the future happiness and prosperity of our country.

With a law on the statute book of the state permitting a sexualization of the criminal, the idiot and the degenerate, and a strict mar-

riage law that would allow no marriage license to issue to any but sound and sane people, soon the atmosphere would clear and no longer would our courts be busy granting divorces, which can be had for the asking, thus destroying all that is sacred in the marriage rite and pure and holy in the home.

I have briefly suggested what I conceive to be the greatest triumph the medical profession has made since McDowell revealed to the world that the operation of ovariotomy, in the hands of skilled physicians and surgeons, could be made a perfect success, and this scientific performance be accomplished in the face of an angry mob. But to-day a monument stands over his pulseless dust to mark the triumph of his glorious achievement.

Since then, year by year, our profession has advanced. Year by year it has demonstrated that it was susceptible of being made an exact science, and Dr. Koch's discovery is probably the widest stride the profession has made along scientific lines in all its history.

His discovery not merely revolutionized medical science, but placed it upon an "Appian Way," inviting those who practice medicine to yet greater and higher triumphs in the future. While we may not hope to corral the human race in every civilized land into "happy valleys" like that once inhabited by "Rasselas," it is not the vision of a mere dreamer to hope that physicians in this and every other civilized country can by an intelligent and progressive prosecution of the science of medicine direct peoples of all lands to a safer and more reliable road; to a better and more certain path to health, physical life and good citizenship, and the science of preventative medicine, in my opinion, unerringly points the way. Whether our profession will prove equal to this humane and greatest of scientific achievements, remains for the future to disclose.

Another underlying thought, which should not be overlooked, in this connection, is this: while medical science does not have to deal directly with political or industrial problems, the fact remains that in this many-sided government in which we live, the medical profession can, and it ought to prove the greatest power not merely for the preservation of national health, but for the promotion of good government.

In these modern times, when commercial greed, with gigantic monopolies in the forefront, throng the highways of commerce and trade, and where fabulous volumes of capital have been congested into a few hands, the patriotic citizen, who loves his country, ought to pause and reflect that if we are to preserve our free institutions; if we are to perpetuate that liberty and independence, bequeathed to us by our revolutionary ancestors, we

must see to it that the citizenship of our country represents, not merely "sound minds in sound bodies," but an intelligence and patriotism which will steer us off those disastrous breakers, on which the cherished hopes of ancient free commonwealths in the past have been wrecked for no free government can long exist if the ranks of its citizenship are crowded with degenerates or perverts.

If we are to successfully deal with those gigantic corporations which appear to have so completely taken possession of the commercial and physical enterprises of our great country, we can only hope that such a result can be consummated by those who determine all issues with their ballots at the polls.

No country can be great or free where its citizenship crouches under the shadows of degeneracy, ignorance and crime.

A lofty citizenship, a patriotic citizenship, and a citizenship sure to guarantee the best results in a free republic must be an intelligent citizenship.

The medical profession holds in the hollow of its hands the possibilities of becoming the chief leader in developing such a citizenship.

I do not doubt that in the coming years our profession will go forward, that it will not merely warn the rich and the poor alike against those insidious waves of disease which constantly lash against the pathway of all human flesh, but that it will set its signal corps upon the mountain ranges of a higher and better life, and thus, not only render invaluable services to those who seek its aid to be protected against disease, but that it will materially aid in the preservation of that liberty bequeathed to us by the fathers.

But these triumphs of our profession which I so confidently predict will not be made by the beat of drum, the blare of trumpets, the crash of musketry, nor rattling swords, but silently, patiently, energetically, intelligently, and scientifically, so that at last the fact will be an accomplished one that the medical profession is not merely an exact science, but that its blessings to mankind and to government alike will be entitled to go ringing, sounding down the ages to the remotest generations of mankind.

DISCUSSION.

H. P. Sights, Hopkinsville: I can hardly refrain from saying something on this subject, and especially after listening to the able paper portraying the evil results, including the conditions in our State, as the doctor has done in his paper.

I would like to emphasize one point in the paper, and that is the moral side of this propagation of degenerates, idiots and criminals. I want to say, my observation, and it is the observation of every medical man in our State, has been that nearly all of the real chronic diseases we have

emanate from a condition of degeneracy. There is nothing that provokes criminal conditions more than an unhealthy condition of parentage. I believe that a perfectly physical man can be moral and will be moral, and I believe that nearly every immoral element in a man's nature is due to some former disease, to some hereditary condition. I cannot, from my knowledge of the human system, believe that a good healthy man mentally and physically, has a tendency to immorality. If that is true, and if we can, as the doctor has suggested, bring about a condition that will make perfect manhood and perfect womanhood, we will do more to prevent criminals than any laws or prisons that can be established in our country.

Another condition that he refers to is the saving of expense. There is no question but if we go on this matter in the right way and in the right spirit, as it is our duty to do, we can accomplish something. Nobody can do it as well as we can. Nobody but the medical profession of the State can take these matters up and have legislation that will correct the condition, because the people sit back and wait for the medical profession to make advances towards the perfecting of the human system. If we do that, and it is our duty, we will be saving more financially than any other element in our State could do.

I am enthusiastic on the subject of asexualization. I believe that the practice of this kind of surgery ought to be undertaken with a view to perfecting human beings, and there is no other way of doing it. As I said in my paper regarding the chronic insane, there should be no progeny at all from them, and while it looks a little hard to carry it that far, there ought to be some means of preventing an increase of these people under those conditions. I am sure, that his reference to a rapid increase of idiocy is true. I believe people with a low form of mentality produce more rapidly than any other class of human beings, and if there is anything that can be done to correct this condition, I think it is a commendable thing to do.

W. L. Heizer, Bowling Green: I feel sure from my knowledge of the attitude of the physicians of the State that no paper that has been read at this meeting of the association will be more widely read than the one that has been contributed by Dr. Ellis, because I know this subject is dear to the heart of the profession of Kentucky. We have need for State cooperation in public health work, and we welcome this paper, and I am sure we shall profit by its recommendation.

To my mind the reason we have so many evils existing is because of the fault of our system of education. We have boys running away from the farms, the most productive field for existence we have to-day who are taking up street car jobs and forty dollars a month clerical positions. It is the fault of our system of education that they

are led away from the things they ought to stick more closely to. Women are reared in a butterfly sort of way, with no responsibility of domestic life. Our educators realize that fact. Diseases are prevalent. Typhoid fever is spread far and near; tuberculosis is spread indiscriminately because it is the fault of the system of education and the people of the State have begun to realize this and to correct it, in a measure, by the establishment of two normal schools in the State, eastern and western. In these schools domestic science is taught. The girls are taught how to make dresses, how to cook, and how to conduct homes for the people of the State. The boys are taught elementary agriculture, how to test the seeds, how to reap the product of their knowledge in one year. All these things will help to prevent diseases by educating the people. The greatest fight lies with the normal schools of the State, lies with the ministers of the State, and with everyone who is in a position to educate the people. To the individual physician possibly it lies more closely than to any other class of men in the State. They must act while the mind is in a receptive condition. Therefore, I think with proper co-operation of the forces in one generation we can so educate the people as to reduce the death rate to eighteen per cent., in tuberculosis one-half, and we can eliminate one-half of our typhoid fever and the other diseases known to be germ diseases. As soon as the people realize the material basis on which the prevention of disease rests, just so soon will they fight against those conditions which bring us so much mental, and physical suffering and distress. There is no question about this in my mind. It seems to me, the ignorance and superstition in medicine is a realization of the fact that they recognize no tangible basis for the spread of disease. They look upon it as a visitation of divine Providence or of the devil, and just as soon as they realize the physical basis of disease lies in the germs of disease, they will fight against the spread of diseases. We have the National Association for the Study and Prevention of Tuberculosis, we have Anti-Typhoid, Fever campaigns, we have tuberculosis preached in the pulpit, and we are gradually educating the people to prevent these diseases in that way. Then, it seems to me, if we could go before the teachers of the State and show them why it is necessary to teach these things, show them it is necessary to link elementary agriculture with domestic science and with preventive medicine, and make school life a part of home life, we will have struck the keynote of these things.

I would urge the physicians of Kentucky to take every opportunity that presents itself to go before the teachers of the State and urge the adoption of the individual drinking cup; tell them if we do that it can be made a basis for a public health talk on Friday afternoon. We

should show them how to make individual drinking cups, and teach them how diphtheria, typhoid fever, scarlet fever, and whooping cough can be communicated in this way. The sanitary drinking cup can be made the basis for health lectures to be given the children once or twice weekly, as the case may be. Tell them that the State Board of Health is issuing a bulletin monthly which will contain articles that deal with public health questions, and give them lectures in such form that they can give it to their children. Urge ministers of your section, who have at least a little time to give to these things, to devote a day to one of the preventable diseases, beginning with tuberculosis and running down through the list. It would seem that in just a short time, in a few years, as soon as the rising generation reached manhood, we will have eliminated these diseases and the patent medicine evil and the others we have with it. We have not been as successful as we might have been in this work because people have not been educated as to the dangers of these things.

In the prevention of typhoid fever there is one practical point I desire to mention, and that is to use fly traps. In one town in this State they use such traps and that town is freer from flies than any other town in this State. Practical things like that, if brought to the attention of the people, will do much good. Flies are a potent means of carrying typhoid fever.

J. S. Lackey, Lakeland: I would like to make a few remarks on this subject. I want to make reference to a few points in the excellent paper of Dr. Ellis.

Many years ago, as you know, it was supposed that lunatics were cast out by the devil and were treated as though they were not human beings. Later on it was supposed that lunacy had reference to the moon; that the mind was supposed to be affected by the moon. Later on we began to recognize lunacy as being due to some pathological condition, and I now feel assured that almost all of our prevalent cases of lunacy are caused by some pathological condition. I have had quite a number of cases in my section that were caused by malaria. They were really crazy people, but I have treated a great many of them for malaria and have relieved many of them. I am speaking of a local condition that prevails on the Cumberland River. We scarcely have a case of lunacy that does not depend upon malarial poisoning. I do not believe in the hereditary phase of it. I thought it got into the family and would run through it and from year to year there would be some member of the family attacked by lunacy. I have a very dear sister who is a lunatic, but I am certain she was attacked at the start with a very malignant form of malaria. She is now in such a favorable condition, thanks to Dr. Sights, that she may soon be removed from the asylum. He tells me that she has greatly improved.

I take this opportunity to say that there has been a great improvement in the asylums and the conditions therein at Hopkinsville. I have visited the asylum at Hopkinsville and know there has been a great improvement in the management, and while I am not going to take issue with the gentlemen who have preceded me, I do say that great things can be done for the lunatics by proper management in hospitals, and I think they ought to be considered hospitals. We know very well that what has been said about idiocy is all too true, and we know that the habits of the men, that immoral practices contaminate the offspring, but, at the same time, a great many of our lunatics—I will say almost all of them—are pathological subjects and can be treated and relieved. There are certain families that are easily affected by tuberculosis, but I have lost my faith in the old idea of the heredity of tuberculosis almost entirely. I do not believe we can have a case of tuberculosis without the tuberculosis germ. It is necessary to have the germ in order to contract the disease, but there are some individuals who are more susceptible to the disease than are others.

J. E. Kincheloe, Breckinridge: I did not hear all of Dr. Ellis' paper, but it seems that the discussion has been directed very largely to the question of training the people so as to prevent disease.

There are two very important points that have not been touched upon, namely, food and dress. We as a nation of people, study science; we study enlightenment; we study physiology and hygiene, and we practice heathenism. We make fun of the flatheaded Indians; we talk about them in derision; that they carry things on top of their heads in order to make them flat. But what do we do? We have the poor fashion that binds the waist of the woman and forces down all of the abdominal organs, interfering with the chest and the whole system, thus making a weaker woman, a weaker man, and this is the source of a great deal of trouble. Why do our gynecologists have so much to do today with women? It is because of our cruel fashion. That is the source of the trouble, and it is up to the doctor to educate the people along this line.

Another point is with reference to eating. As I have said, we study science and enlightenment, but we practice heathenism. We eat too much. We would not take a fine colt and raise him and have him eat all the time. We would be afraid to do it. But what does the mother do with the child? She stuffs the child from the time it is six weeks old. Not infrequently you will hear a mother say, if my child does not eat bacon and beans, it will starve to death. Children are stuffed from the time they are six weeks old. We have to be very careful with babies because we do not raise them right. We do not feed them on breast milk as frequently as we should. The American people are a set of gluttons. We fill

our stomach, we over-eat, and what is the consequence? We have auto-intoxication. We fill the system with too much fat, so that the germs of consumption and of pneumonia gather upon us. If we poison the source the stream is bound to be poisoned. While it is a good thing to educate the people, still we practice heathenism, and we do not put into practice what we preach.

POST-OPERATIVE TREATMENT FOLLOWING PROSTATECTOMY.*

By LEWIS WINE BREMERMAN, Chicago.

Much has been written upon the relative merits of the various operative procedures for the removal of the prostate. Many statistics have been compiled to prove which is the better—the suprapubic or the perineal route. It is surprising, upon looking over the literature on prostatic work, how little has been written regarding the after treatment of prostatectomy, which to my mind is vastly more important than the operative technique. It matters little which operation is performed, if the patient recovers and is relieved of the annoying urinary symptoms, his recovery, in my opinion, depends upon the care and attention given him after the operation.

The post-operative treatment may be divided for convenience into three stages:

First, the period immediately following the operation.

Second, convalescence.

Third, the period covering, at least, six months.

During the first period, that immediately following the operation, the most important elements to be guarded against are shock, hemorrhage, anuria and sepsis.

In considering shock and its prevention I will be compelled to dwell for a moment upon the preparation of the patient preliminary to the operation. I will consider the question of anesthesia which, in these old gentlemen upon whom prostatectomy is performed, is of paramount importance. In clean cases, that is, when there has been no existing cystitis either of long or short duration and other things being equal, the operation may be performed at once. If the bladder has been infected more than a week or two preliminary treatment, for the purpose of rendering the field of operation as aseptic as possible. It is well also to institute constitutional treatment for the purpose of increasing the resistance of the patient.

As little preliminary work as possible should be done upon the patient in the operating room, and everything made ready for the operation before the anesthetic is given.

*Read before the Kentucky State Medical Association, Paducah.

thus shortening the time of the anesthesia, thus reducing the possibility of shock. It is my custom to have the bladder irrigated and filled and have the skin surface cleansed, just prior to the beginning of the anesthetic, the bladder being filled with formalin in solution of 1-4,000, and the skin surface painted with tincture of iodine.

It has been my practice in the majority of cases upon whom I have operated to use nitrous oxide gas and oxygen as an anesthetic. This is safe, rapid, and reduces to a minimum the chances of shock and anuria, and also, as may occur in either anesthesia, prevents to a great extent the dangers of pneumonia. I feel that one of the exciting causes of shock, particularly in the aged, is the persistent nausea, vomiting and straining which follows ether or chloroform anesthesia, this is entirely eradicated by the use of gas and oxygen. The patient fully recovers before leaving the operating room and is free from the annoying untoward conditions which are so greatly feared when other anesthetics are employed. I am compelled, however, to call attention to one class of patients where gas and oxygen anesthesia is contraindicated. If the patient has a myo-carditis then ether is the safest to employ. Gas and oxygen anesthetic is not an easy one to administer and for the best results it must be left in the hands of the expert. It is impossible for the interne or one not familiar with this form of anesthetic to know the proper mixtures, and to readily recognize untoward conditions.

My anesthetist has given many thousands of gas and oxygen anesthetics, and I must admit I employ it in cases where ordinarily this anesthetic would be contraindicated. Even when ether or chloroform is used I feel that in these cases in old men it is the safest plan to employ an anesthetist who has had much experience, for the patient should be kept under the influence of the anesthetic by the use of the smallest possible quantity.

Immediately following the operation and continuing for twenty-four hours hot salines per rectum, by the drop, are employed. This is done in every case, influencing a decided action upon the post-operative shock and anuria. Strychnine is administered in conjunction with the saline for the first twenty-four hours if it is indicated.

After the prostate has been removed, a 32 F. sound, or one as large as the calibre of the urethra will allow, is passed into the bladder, a meatotomy having been performed if necessary, to allow the passage of the instrument. The region around the internal urinary meatus is carefully examined, if there are any fragments of tissue these are removed. The bladder then is irrigated with hot formalin solution 1-4,000, which will, as a rule, stop the

bleeding, only occasionally is it necessary to pack the bladder to control the hemorrhage.

A drainage tube about 27 or 28 F. in size is inserted, this with thick walls to prevent collapsing, the bladder closed snugly around the tube, the structures are brought together with as few sutures as possible, reducing chances of infection. The tube is brought out of the upper angle of the skin incision.

The bladder must be drained as the process of drainage is the most important phase in the after-treatment of the case, as upon perfect drainage depends almost entirely the success of the operation, for by perfect drainage we minimize the danger of shock, anuria, sepsis, and hemorrhage. Drainage in these cases has been the bugbear of operators since prostatectomy has been classed among the scientific, justifiable operations. All varieties of drainage apparatuses have been devised. Most of these have been discarded as useless. Some operators use nothing but a tube which drains by gravity, others recommend the use of a tube of large caliber, through which if the drainage is not perfect, blood clots, etc., may be removed by the nurse in charge with a long pair of forceps, increasing by this method, as one can readily see, the chances of infection.

The author has devised a drainage apparatus which carries out all of its function automatically and with precision, producing absolutely perfect drainage. The apparatus is shown in the cut on page 111.

After the patient is placed in bed the tubing is connected with the drainage tube from the bladder. The Y-shaped tube F must be below the level of the patient lying in bed; the reservoir A filled with water, the stop-cock B turned so that the water will drop slowly into the cup C, which, on being filled, tilts and empties itself into the funnel D. The water running down the long tube E into the Y-shaped tube F forms behind it a suction which causes a siphonage of the fluid in the bladder. This siphonage may be regulated to occur at any given interval by arranging the flow of water from the stop-cock B which flows into the cup.

I am sure that those who are doing much bladder work have met with the same difficulties in perfect drainage as I have met with in my work, and that if they will take the occasion to use the apparatus which I have devised they will be satisfied with the results.

By perfect drainage you render your patient comfortable, the bladder does not become distended, clots can not form, the dressings are dry, the bladder can not fill up and run down alongside into the dressings, thus irritating the wound, which prevents healing, and can not trickle into the tissue of the pre-

vesicle space and endanger the patient to sepsis. I have used this apparatus in a large number of cases and feel, without a doubt that my satisfactory results have been due almost entirely to perfect drainage.

Apparatus for complete drainage of bladder following suprapubic or perineal cystotomy; A, reservoir for water; B, stopcock for regulating the flow; C, cup weighted in the rear to hold in place when empty; D, funnel to catch the water when the cup tips on being filled with water; E, long tube which connects the funnel with the Y-shaped glass tube; F, Y-shaped glass tube; G, tube connecting the drainage tube from the bladder with the Y-shaped tube.

I might call attention to another important feature of the drainage apparatus herewith described; with its use one can readily tell how much urine the kidneys are excreting. This is accomplished by measuring the fluid in the reservoir, also the urine blood and water in the receptacle under the bed, subtracting this former amount from the latter, the difference being the urine and the blood. This knowledge is very essential as it is an aid to know the functional capacity of the kidneys.

I might suggest a precautionary step to be taken in regard to placing the drainage tube in the bladder. Care must be taken that the end of the tube does not come into contact with the floor of the bladder.

Two cases of anuria have occurred in my practice, produced reflexly by irritation of the tube in the bladder, it was necessary in both cases to remove the tube. Shortly afterwards there was a copious flow of urine, there had been no urine in the bladder, as was shown upon removal of the tube, and the tube was proven not to have been blocked in any way. It has been my practice for several years to endeavor by the recognized tests to estimate the functional activity of the kidney, not only in cases where surgical work is to be done upon the kidney, but whenever it is necessary to operate upon any portion of the urinary tract. It is very important in operations upon the prostate, particularly when the condition has been of long standing and there is danger of kidney complications.

During the first twenty-four hours the drainage apparatus is so set that it will empty the bladder completely every five minutes, during the second twenty-four hours every ten minutes, thereafter every fifteen minutes. The apparatus will carry out its function no matter what the position of the patient, he may be in the dorsal position, may be reclining in bed, or sitting up in a chair. The apparatus is employed for five or six days, when the tube is withdrawn. During the first twenty-four hours a metal catheter 28 F. is passed per urethra into the bladder and the bladder irrigated with formalin solution 1-4,000, followed by injection through the catheter of one of the silver salts. I prefer a 2 per cent. solution of nargol, which has acted most favorably in my practice during the last six or seven years. The outflow of solution is through the drainage tube. This procedure is carried out daily for three weeks. During the third twenty-four hours the patient is allowed to sit up in bed and the next day, the fourth day, he is allowed to sit up in a chair. He is encouraged to sit up daily and walk about as much as he can, usually within three weeks the patient may leave the hospital.

From the time the patient leaves the hospital until at least six months have elapsed he should be kept under observation. This sometimes is difficult, owing to the fact that the patient comes to us from a distance, however, his treatment should be carried out by his physician.

I suggest irrigation of the bladder at least once a week for several months, oftener if there is evidence of pus in the urine, the urethra should be dilated occasionally. After six months I insist upon a cystoscopic ex-

amination, and if the bladder is, at this time, normal in appearance, the patient in a comfortable condition, he is discharged. Keeping the patient under close observation is very important as complications are so apt to occur. We are familiar with the frequency with which there is the formation of vesicle calculus following operation, especially in septic cases. Careful treatment will prevent all these untoward sequelae.

So many patients come under my observation as cured, suffering with symptoms nearly as annoying as prior to the operation, pain, frequency, both by day and night, and with a severe cystitis, where if proper care had been given after the prostatectomy had been performed, there would have been, in the majority of cases, excellent results.

I might suggest that if a well-outlined course-treatment be instituted along the lines indicated above, that the result will be surprising. The patient will be more comfortable during the first few weeks following operation, and when he is allowed to depart he will do so as nearly recovered as it is possible to get these old men.

THE NEWER METHODS OF TREATMENT OF DISEASES BY HYPODERMIC MEDICATION.*

By CURRAN POPE, Louisville.

You will, of course understand that in presenting this little talk to you concerning the newer methods of treatment of disease by hypodermic methods, I am simply going to give you in an impromptu way the results of a long number of years of experience I have had in treating the anemias and other diseases by hypodermatic medication.

I would like to say at the outset that I am wedded to hypodermatic medication of all kinds, and believe in hypodermatic medication we come nearer to getting the *actual* action of the drug *physiologically* than by running the risk of having it undergo transformation in the digestive tract, as well as the uncertainty of absorption. Essentially the effect of medication does not occur until it is within the mucous membrane of the gastrointestinal tract. Until it has been literally digested, assimilated and absorbed, you cannot possibly expect to get the physiological action of a drug, nor can you get its influence upon pathological conditions until that has come about.

We know that the chemistry of digestion is a somewhat unsettled and unfixed proposition in a great many individuals, and consequently medicaments introduced per *orem*

are apt to be changed and be absorbed in a different state in which they have been prescribed. For that reason, wherever it is possible, I am inclined to believe that the administration of a medicament by means of the hypodermatic syringe is not only the safest but the surest way of getting at the influence of the particular drug upon the patient.

Now, coming more particularly to a consideration of the administration of, for instance, the irons in anemias, I do not hesitate to say that, I believe, I have used iron hypodermatically in the anemias longer than any man in the State of Kentucky. I have been using iron hypodermatically for twelve or fifteen years. For a long time I had imported for me the Italian ampules of the various forms of iron, in order to administer the arsenate and citrate of iron. I have found the citrate of iron hypodermatically administered far more satisfactory and certain in the anemias than any other form of iron, although in certain cases that point toward chlorosis we will find a combination of the citrate of iron and the arsenate of sodium or arsenate of iron of great value when given hypodermatically.

Passing to another condition I rarely ever, in my specialty, attempt to treat syphilis by any other means than by hypodermatic medication. I meet with many syphilitic affections of the nervous system in my practice, and am wedded to the hypodermatic administration of mercury, preferring the salicylate to every other form. I have tried a great many forms from gray oil to the bichloride and other preparations, but have finally settled on the salicylate and use it almost exclusively, alternating it now and then with the administration hypodermatically of the trioxide of arsenic, which is the old arsenous acid. I believe we get quicker, better and surer results from the hypodermatic administration of these drugs than we would by the long continued administration of mercury by the mouth. In nervous syphilis, particularly in syphilis of the brain and cord, we often find our patients anemic and run down, speaking in general terms. I have always felt that by giving mercury hypodermatically I save my patients' stomach, so that I was able to treat him dietetically just exactly as I would treat a tuberculous patient. In other words, while trying to overcome the toxemia of syphilis I have his stomach for the food that would act as a reconstructive, and these old cases of cerebral and spinal syphilis are benefited by careful dietetics, careful rest, careful attention to elimination, just as a tuberculous patient would be.

With regard to atoxyl, I was one of the first to employ it in this section of the country; I

*Read before the Kentucky State Medical Association, Paducah.

had some of the first tablets which were brought to this country.

I was much interested in the publication concerning atoxyl in one of the German medical journals, and hearing that Sharp and Bohne had these tablets I wrote to them to get some. I used them, but I must say, that I am afraid of atoxyl. I have seen some disagreeable results from it, and I believe we can get as good and far safer returns in the administration of arsenic hypodermatically than from the use of the old trioxide, which produces bad effects, gives the full arsenical influence and avoids paying the high price for a rare drug, and that is some consideration, for atoxyl and some of the other preparations are expensive.

I have used caedylate of sodium considerably. I wish I could give practically all of my medicines by means of the hypodermatic syringe.

Now as to the value of hypodermatic medication in the anemias. We should judge of the value of iron not only by the clinical symptoms but by careful blood tests as well in addition to a careful study of the patient, and his clinical symptoms. The moment you begin to divorce the patient and depend entirely upon your laboratory work, that moment you are going to make mistakes, but at the same time a man can check up and watch the work, the results of his work, in a given case by means of blood counts, and by means of his hemoglobinometer, and from time to time learn the effects of the remedies that he is administering.

As I said at the outset, I believe the hypodermatic administration of iron and of arsenic will not only bring surer results, but will bring better results, without the slightest harm to the patient. There are a great many patients who say they cannot tolerate the iron. I have found many who said they could not, and yet who took iron well hypodermatically administered. As to whether their inability to tolerate the iron was a psychic problem, or whether there was by the iron formed in the digestive tract some condition that affected them unfavorably, I do not know. I am prepared to say, but I do not say that a great many of them would complain of vasomotor symptoms, of flushing, fullness of the head, a disagreeable feeling in the head, and they would say, "Doctor, I cannot take iron." I have said to them, "That is all right; we will give you something else. We will not give you anything by the mouth. We will give you some hypodermatic medication," and in giving them the iron hypodermatically they have not only tolerated it, but have assimilated it, and have been benefited the blood count and hemoglobin rising under its administration, and I have rather thought

that it was largely a psychic influence of the iron. It is always well to commence with comparatively small doses of arsenic. There is no question but what a great many people have an intolerance to arsenic. I have found quite a number, and I would recommend to any one starting to use these drugs hypodermatically, that they start with a small dose of the arsenic. By starting with a small dose and gradually increasing it is much better for the patient. I usually employ daily injections of both iron and arsenic or the iron and arsenic mixed, and sometimes I employ iron, arsenic, and some form of the glycerophosphate, in that way getting extensive medication in one single hypodermatic administration. But it is a good plan never to start with a maximum dose. It is better to start say with a third the first day, a half the next, two-thirds the next, three-quarters the next, and so on, until you reach the maximum dose you care to give. If given in this way, you will find it brings about a gradual tolerance on the part of the patient to the drug until you reach the maximum effect, and until you gain the desired physiological influence of the remedy.

Gentlemen, I trust you will pardon these impromptu remarks I have been making. I have had really no chance to make any preparation upon the subject and I have only spoken at the request of the president, in order that the vacancy on the program might be filled. I have tried to give you as far as I could in condensed form the practical experience that I have had in the last ten or twelve years with the administration of these remedies by the hypodermatic needle. I thank you.

DEEP INJECTIONS OF ALCOHOL FOR PERSISTENT NEURALGIA.*

By E. A. STEVENS, Mayfield.

To those who are familiar with the treatment of persistent neuralgia by the deep injection of alcohol as practiced by Levy and Baudoin of Europe, and Patrick of this country, this paper has but little that is new. Its purpose, however, is to show that this work can be done by the general practitioner if he knows his anatomy, if a specialist is not available. Many of these cases are permitted to suffer for years because they are not able physically or financially to go to the specialist. Many of these people are between seventy and eighty years of age.

The men above mentioned have used slightly modified alcohol for the injecting fluid with only slight difference in the formula.

*Read before the Kentucky State Medical Association.

†Admch.

Osmic acid has been used, but alcohol seems to be the preferred fluid. I am indebted to the writings of Dr. Patrick, of Chicago, for the technique of the work on the different divisions of the trifacial nerve. I also use the solution which he recommends, but both method and solution he says he got from Levy. He uses 85 per cent. alcohol (not absolute) with four grains of cocaine to the ounce. He first used a little morphine and chloroform in the injection, but he has abandoned them and thinks he has less trouble than when he used them as the morphine especially produced troublesome vomiting in some cases. He uses a blunt needle one and five-tenths millimeters in diameter, ten centimeters in length, with a stylet to avoid puncturing a blood vessel. The stylet is withdrawn after the needle is started. It appears to me that this needle is so large that it is more painful than is necessary, and it has been abandoned for a sharper and smaller needle without stylet by most of the European physicians. For many years in different ways injections have been tried for this malady, usually attempting to inject the nerve at its exit near the surface instead of at its deep exit from the cranium. This method gave partial relief in many cases, but was seldom an entire success for any length of time.

The present method attempts to inject the second and third branches of the trifacial nerve at the point where each makes its exit from the cranium, namely: at the foramen-ovale for third and rotundum for the second. When you go to examine the base of the skull you will find that the external opening of the foramen-ovale is not so hard to reach and is not surrounded by such important structures as the rotundum which opens into the sphenomaxillary fossa which is practically continuous anteriorly with the sphenomaxillary fissure, which is a passage-way into the orbit, and if the point of the needle goes too far forward it may enter this cavity through this sphenomaxillary fissure and certainly might result in damage to the tissues in the back of the orbit. Dr. Patrick mentions a case where the patient cried out when he pushed the fluid into the tissues that it produced such a queer feeling in his eye, and the resistance to the pressure of his syringe seemed to suddenly give way. He seemed to think he was using too much pressure on the syringe, but to me it seems more probable the point of the needle had entered the orbit through the sphenomaxillary fissure instead of going into the sphenomaxillary fossa. He says it did no serious harm.

The passage of the needle for these deep injections is quite painful, but not enough so to render a general anaesthetic advisable as you need the patient's sensations to guide

you. I give the technique of these injections as I find very few books contain it. I have not seen a text-book that contains a sufficiently lucid description of it to make its execution easy. Dr. Patrick's instructions for reaching the third division of the trifacial nerve is as follows: Find the descending root of the zygoma, which can always be felt and corresponds practically to the anterior bony edge of the auditory canal; measure two and one-half centimeters forward along the lower border of the zygoma; insert the needle at this point and push it in four centimeters, hugging the base of the skull and going slightly upward and backward; at the depth of four centimeters you should reach this nerve, and if you strike it with the needle the patient will likely say you have hurt his face or jaw, which will enable you to know beyond question that you are at the right spot. Two cubic centimeters of the above mentioned solution is then injected with moderate force into the tissues. It is accompanied by a slight increase in the pain which rapidly subsides, and in some cases, the most favorable ones, the paroxysms cease at once. To reach the second division at its exit requires more skill and more accurate knowledge of the anatomy of this region. To reach the nerve at its exit from the foramen rotundum it is necessary to get the tip of the needle into the sphenomaxillary fossa as it is in this space where you must find the nerve. To find this fossa draw a perpendicular line along the posterior edge of the frontal process of the malar bone as it ascends to articulate with the external angular process of the frontal bone. Where this line, if prolonged, would cross the lower border of the zygoma would be one-half centimeter in front of the point to insert the needle. Direct it slightly backward and upward so it will reach a lever of the inferior extremity of the nasal bones when it reaches a depth of five centimeters. If the needle is pushed too far to the front it will strike the posterior wall of the superior-maxilla, and if too far back, the pterygoid plate of the sphenoid before the needle gets in near the five centimeters. If you strike either it is best to almost withdraw the needle and try again. If the needle goes deeper than five centimeters it means you have either gone through the thin bones into the nasal cavity, or if too far in front, into the orbit. If it enters the sphenomaxillary fossa when it reaches the depth of five centimeters it meets a firm resistance and at this point you insert the fluid. The first division has been injected at its entrance into the orbit at the point where it left the sphenoidal fissure. That makes it necessary to pass the needle through the orbit very near to the eyeball and is not considered safe. The best plan seems to be to use the old

method on the first division and inject it at the point where it passes through the supra-orbital notch.

My experience does not cover many cases, but a few months experience with one case severe enough to make the patient moan with pain with enough vigor for you to hear him before you get out of your buggy when you make your visit will soon lead you to feel that your observation is sufficient. In my judgment all of these cases usually classified as chronic neuralgia are cases of neuritis, and I think that is the general opinion of those who have closely investigated the subject. Of course, this does not include those cases, the result of gross disease of adjacent organs. Neuralgia was originally believed to be a cry for more blood and better blood; but we know now that it was simply an inflammation of the nerve itself.

My first experience with chronic neuritis of persistent character was a case of sciatica in a man who had acquired the morphine habit. The last time I saw him he retained both the disease and the habit. The next was a woman fifty-five years old with neuritis affecting the second division of the trifacial nerve. I heard her screaming with pain before I reached her house. I saw her in consultation after many weeks of suffering. I made an incision down to the infra-orbital foramen and cut the nerve at its point of exit after stretching it as much as I thought it would bear. Her pain was better for months, but it returned quite severe in a year and I injected it with chloroform at its exit this time. The injection gave great pain and was followed by a marked induration that was slow in going away. It seemed to give some relief, but she continued to have attacks until she died a few years later with some acute trouble, but she was never quite as bad as she was before the first operation.

The next was a woman sixty-eight years old with a severe neuritis of the second division. I operated by incising the nerve at the infra-orbital foramen which gave her fair relief for a year, but it has returned but never quite so bad, not bad enough for her to be willing to have the deep injection made. Vibration and the analgesics gave some relief and she had nothing else done of an operative character.

The first case of injection with the alcohol mixture above referred to was in a woman of thirty-five years of age who had always had good general health but for two years had been suffering with pain in the third division of the trifacial, growing worse until she had had most of her teeth removed from the lower jaw without any improvement but a gradual increase in the severity of the paroxysms. I treated her for several months with medicine

internally vibration, and other things, only to see her grow continuously worse. I finally persuaded her to allow me to use the alcohol by deep injection. A small, blunt, long hypodermic needle was passed according to the technique given above, and just at the point where I expected to strike the nerve she gave a sudden cry of pain and said that I had hurt her jaw. I injected at this point. There was some shock attending it, marked pain, slowing and weakening of the pulse and a moderate perspiration. This lasted some five minutes when it entirely passed away. She said that her lower jaw and tongue were numb. The pain stopped almost immediately and while she says she occasionally experiences a sensation of heat in the jaw and an occasional mild touch of pain it is not enough to distress her, and she seems practically as well as ever. She was confined to her bed at the time of the injection and had been some days before. It has been fourteen months since this was given and she seems to all appearances perfectly well.

The second case was a lady seventy-one years old, six years standing, neuritis of the third division of the trifacial. I gave the injection in my office. She was able to get up in a few minutes and go home. Says she has never had a pain from that day to this. That was about three months ago. She had reduced in flesh from 180 to 120 pounds. She says that the treatment is the greatest thing in the world. Her family said that her moanings and distress were so great that it kept every one miserable around her.

The third case I saw with Dr. Jackson, at Arlington, a woman about fifty years of age with involvement of the trifacial nerve. I injected the second division at the point above mentioned, at which time she cried out that I had put the medicine into her nose and upper lip. Knowing that it could be put into the nose, I thought I had pushed my needle too far, but when she said part went into the upper lip I knew that it was but the sensation of the medicine upon the nerve itself. Within a few minutes after the injection she said her face was easy but there was still a pain over the eye running back toward the ear. Hoping that it would not be necessary to inject the first division, I did not inject it but left the case with Dr. Jackson with the understanding if she was not relieved in twenty-four or forty-eight hours that he would inject the first division at the supra-orbital notch, which he reported to me that he had to do. He told me in a later report that she had apparently entirely recovered.

These are all the cases of injections of the trifacial that I have to report, but believing that practically the same condition exists in sciatica that did in neuralgia of the trifacial

nerve, I tried this treatment on three cases of sciatica using a needle of a similar character to the one I used in the trifacial injections, making it a little blunt so that I could feel when it struck the white fibrous tissue of the sciatic nerve. My effort has been to pass the needle through the nerve where it passes between the tuberosity of the ischium and the great trochanter. A blunt needle can be felt tearing the fibres of the sciatic nerve quite sensibly as it passes through. As soon as the needle perforates the nerve I inject the same quantity, two cubic centimeters that I injected into the trifacial. The reason why I do not try to put it into the nerve itself is I know that it may produce at least a temporary paralysis and as the sciatic is a mixed nerve you do not care to paralyze the motor part. It is more difficult to paralyze the motor nerve than it is the sensory as the efferent current is much more powerful than the afferent current. There seems to be an affinity for alcohol in the nervous tissues and if it comes in contact with it the nerve tissue seems inclined to absorb it. The lecithin seems to be the most important part of the nerve. Alcohol dissolves the lecithin and there is reasonable ground for believing that it acts somewhat like cocaine does in blocking the nerves and producing anesthesia at its points of distribution. Acting on this idea a very short time after I injected the first trifacial nerve with alcohol, I injected the sciatic in the case of a stout young man with a persistent sciatica that had resisted the usual medical treatment. He recovered promptly and his physician who referred him to me says he has had no return of it.

The second was a young man about thirty-five, confined to the bed for several weeks with sciatica. I injected him in the same way. In a few days he was able to be up and has continued up ever since, more than a year, but still complains of considerable pain. This is a case where I think a little more prudence might have led to a cure without an additional treatment which I would advise, but which he has not taken.

The third case was one of a very busy lawyer who was taken with sciatica and whom I treated for about three weeks with the usual medical treatment and vibration. He improved slowly and was able to go to the office but had to lie down most of the time. At the end of three weeks he called me to his home again and I found he had had a sharp relapse and was suffering as bad as ever. I gave him the injection of alcohol with enough morphine for immediate relief, the latter of which he had had before two or three times in this same region. The next day he was able to go to his office and improved rapidly, and he

tells me that he is entirely recovered except for a slight weakness in that leg.

The seventh and last case is one of neuritis of the median nerve, occurring in a drummer who is now about fifty years of age. He has had it for six years. He seemed to get the trouble started in his thumb. He has only one arm and in traveling much of the time had to carry two grips. If any of you will pick up two grips in one hand you will find that one of them will press severely upon the branch of the median nerve which is distributed to the inside of the thumb. Having only one hand it could never get any rest when he was at work, and the continuous pressure set up an inflammation of this branch which extended up the nerve to the shoulder. For six years he has been a great sufferer. I have done everything in the way of medical treatment that I could and he has gotten no relief. The median nerve is made up from the inner and outer cord of the brachial plexus and gets fibres from the sixth, seventh and eighth cervical and first dorsal nerves. Having exhausted everything else, I persuaded him to let me try the alcohol injection on these nerves. My first injection was at the lower border of the axilla, but the axillary artery and the cord from which the median comes lie so close together that it was difficult to inject one without endangering the other. From this injection there was no relief. I then undertook to inject the different divisions of the nerve at their points of exit from the spinal column. I gave him three injections, the last of which was thrown into the sixth division and was followed by partial paralysis of the circumflex nerve. The original pain was much diminished, but the tenderness in the shoulder and arm was much increased. I think the slight paralysis and soreness will soon disappear. Whether the paroxysmal attacks of pain will return with their severity only time can tell. This case was one of a distressing character because it practically disabled the only arm he had.

My opinion of the method of cure or relief in these cases is that it produces a temporary paralysis which amounts to a physiological rest. During this rest the nerve temporarily recovers from the neuritis but being weakened by the previous disease the history of this treatment indicates that it will return in from one to three years after the treatment, though some of them seem to be permanent. There are few more painful maladies and if this will relieve them even for the time mentioned it is well worth the trial. It is not claimed that it will relieve all of them, neither will the operation on the Gasserian ganglion relieve them all, but it seems to give equally as good results as the removal of the ganglion and is much safer, many of them being too

old to have the radical operation performed with any degree of safety.

The question naturally arises, what is the danger in the treatment? Dr. Patrick says practically none. I do not think the danger is great, but I think there is some danger of injuring the eye through the spheno-maxillary fissure when injecting second division, or possibly with a sharper needle penetrating a small blood vessel which might give you a troublesome clot if nothing more, but the relief is well worth the slight risk. A small artery from the superior-maxillary passes through foramen-ovale with the third division.

PROGNOSIS AND TREATMENT OF TYPHOID FEVER.*

By C. R. GARR, Flemingsburg.

There being so many complications and sequela to typhoid fever a prognosis is attended with a high degree of probability.

So large number of factors having a direct bearing on the outcome of this disease the most astute observer cannot foretell many grave dangers that might suddenly arise.

The age of the patient influences our prognosis. The age of least mortality is below 15 years. The death rate is greater in patients past 40 years.

The virulence of the infection is also an important factor. I have seen some epidemics in which most every case was severe, protracted and in which the mortality was higher than in other epidemics the cases of which would run a milder course.

Much depends on the individuality of the patient.

Alcoholics are bad subjects as their tissues and their vitality is at low ebb.

The prognosis is more unfavorable in the obese than in the muscular as it is difficult to control the fever through a thick layer of adipose tissue.

According to the statistics of Shallen¹ season plays an important role in our prognosis. In 68,943 collected cases in Philadelphia in the years January, 1898 to June 1909 the average mortality was 11.75 per cent.

The average number of cases for July was 13 per cent to 17.61 per cent and dropped to 11 per cent, in August and 10 per cent, in September.

The average number of cases for July was 275 while for September it was 450. According to this series of cases the mortality was greatest in July when the average number of cases was fewest.

Pregnancy increases the danger, not so much from the enteric itself as from the re-

sultant abortion which occurs in 65 per cent. of the cases.

Another factor most important in our prognosis is the nursing and treatment the patient has. It is these cases neglected or partially so that increase the mortality.

These cases not properly cared for are subject to hemorrhage or perforation from improper food and to decubiti from a sloven bed.

I have recently lost two cases sheltered in only a shack, every member of the family being sick and without friends and funds, cases which could most likely have been saved had a public nurse or hospital has been available.

Perforation occurs in from 1 to 2 per cent. of all cases and is of greatest significance².

Again our patient may be well through his convalescence only to have an unforeseen relapse or a serious complication or sequela which means weeks of further suffering and possibly death.

Much is being written on the association of the liver abscess and gall-bladder disease and typhoid fever. E. M. von Eberts³, M. R. C. S. (Eng.) has collected several series of cases of liver abscess occurring with or following typhoid. In 200 fatal cases on which autopsies were done at the Pathological Institute of Munich 12 cases of liver abscesses were found.

Dopfer reports 927 cases with 10 deaths of abscess of liver, while Le Grand reports 6 cases of liver abscess in 133 consecutive typhoid in New Caledonia.

There are numerous sequelae, too numerous to detail, a fact which makes our prognosis certain and I shall call attention to but one other, that of typhoid spine.

There are but 82 cases reported. It was first described by Gibney in 1889 and coming on as it does during or after convalescence is one more pitfall to the prognostician.

The usual mortality is estimated at 14 per cent. for Europe and 8 to 12 per cent. for this country by prominent observers.

TREATMENT.

In enteric fever as in many other diseases we who have been practicing longer than we like to tell have seen vast changes in its treatment. This gradual evolution has brought us to a point where we realize that our chief duties in the treatment of this self-limited disease are prevention of its spread, directions for proper nursing and feeding, and a vigil eye for danger signals.

Prophylaxis is accomplished by destruction of all the bacilli in the dejecta of the patient.

The feces, urine and sputum must be disinfected as it is from these a water⁴ supply may become infected.

For disinfection of the dejecta milk of lime should be added to the bed-pan and allowed to stand for an hour. Chloride of lime can be

*Read before the Kentucky State Medical Association, Paducah.

used. This is highly important and one of the physician's chief duties.

The bath water should also be disinfected as this is a source of infection when emptied into the sewer or thrown in the back yard.

The patient must also be placed in a room well screened so that flies cannot carry the infection to food.

If the water supply is already infected all water should be boiled for drinking and cooking purposes.

The bed linen must also be boiled in soda water. Too much emphasis cannot be laid on the disinfection of the excreta and everything else that can carry infection.

In the past few years much has been done towards prevention of typhoid by inoculation with typhoid vaccine. The results of this are best seen in the mobilization of troops, they being subjected to water from many sources.

In the recent maneuvers in Texas typhoid fever has been almost nil, due to the vaccination of the soldiers, and in the maneuvers in Tennessee, as reported by Lyster², typhoid developed only in those soldiers who had not been vaccinated.

This certainly is a great advance over the days of the Spanish war when 86 per cent. of the mortality was due to typhoid fever and one out of every five soldiers was infected³.

The vaccine immunizes the blood against the infection by causing an increase in the agglutinins and opsonins⁴. 100 to 500 millions bacilli are injected and the dose repeated twice three or four days apart. In five or six days sufficient antibodies are formed to cause immunity.

The room should be light and airy. The bed with a firm mattress and instructions given to keep the bed linen smoothed out, and as free from wrinkles and knots as possible for herein lies the prevention of the much dreaded bed-sore.

The patient's mouth should be washed several times daily, sordes cleaned from the teeth and the tongue scraped with a whale bone. A splendid mouth wash is one-fourth vinegar, three-fourths water and a little salt.

The last word has not been said in regard to feeding our typhoids.

The Germans advocate much feeding and from the liter Americans are following them.

Nourishment should be given regularly but little at a time, and as long as tympany is absent the nourishment should be increased.

I am opposed to sweet milk but use butter-milk throughout the course. Chicken-broth, whey, gelatine, the white of an egg beaten and flavored with much brandy, orange juice, lemonade, (sweetened but little), beef tea and a little cream, can be given at intervals of two hours as long as there is no gas. Solid food should not be given. A malted milk tab-

let is often relished by the patient and I've seen it do no harm.

When the fever is normal the diet can be increased each day so that at the end of a week the patient is taking care of solid food with no difficulty.

A dose of oil should be given at the outset but saline enemata daily or every other day are better than continued purgation. The enemata relieved the tympany also.

For the fever the tepid bath gradually cooled seems best. Start the bath with tepid water with a small lump of ice in the bowl. The sponge bath must be repeated sufficiently often to keep the temperature between 101 and 102. In giving a sponge bath the limbs should be well rubbed creating friction which increases the skin circulation and cools the blood as it passes through the capillaries.

In addition to the sponge bath the patient should have a toilet bath with soap and water each day.

For tympany turpentine gtts x and enemata once or twice daily seem best. Some advise physostigmine but I have never seen it do good.

Diarrhea often needs treatment. Camphor, opium, and lead acetate a. n. gr. 1 is indicated, or bismuth and chalk mixture.

Headache is relieved by an ice coil to the head.

As for intestinal antiseptics I'm in doubt whether they do good or not. Salol, acetozone, sulpho carbolates, and many others are advised but my cases seem to do just as well without them as with them.

The heart must be looked after from the start. It is this organ that suffers most from the continued pyrexia.

In severe cases it most always is necessary to stimulate the heart during the third and fourth weeks. Strychnine grain 1-30 hypodermically seems best. Camphorated oil is a valuable adjunct when stimulation is needed in impending collapse.

For hemorrhage—powdered opium or morphine—absolute quiet and no food.

For perforation—surgery.

For the many other conditions that arise systematic treatment.

In conclusion I wish to call attention to the treatment of typhoid fever with vaccine. Walters and Eaton give a summary of 36 cases so treated with the following results:

Average duration of fever with vaccine—15.5 days.

Without vaccine—25.3 days.

Average residence in hospital with vaccine—39 days.

Without vaccine—57 days.

Jos. G. Collison has collected 323 cases treated with doses of various sizes and a mortality

5.2 per cent. He believes it should be used in the treatment as well as a prophylactic.

SERUM AND BACTERIN THERAPY.*

By W. M. FLOYD, Henderson.

In offering this paper upon "Serum and Bacterin Therapy," I wish to disclaim any original contribution to the literature of the subject and also to give full credit for anything of merit that it may contain to those from whom I have quoted liberally.

The current literature upon the subject and especially that found in the *STATE JOURNAL*, *The Southern Medical Journal* and the *Journal of the A. M. A.*, whether in abstract, editorial or otherwise, I have laid violent hands upon. Iron's (of Chicago) article on Serum and Vaccine Therapy and Schorer's Vaccine and Serum Therapy have been carefully gleaned and largely quoted.

If we succeed in condensing the literature at our command and in drawing those inferences that our present light seems to warrant on this most promising field of therapeutics our effort will be well worth while.

Inasmuch as serum and bacterin therapy has for its objective the sensitization of the body complex to enable it to resist or overcome infection and to render it immune to infection for a variable period of time, a study of this subject resolves itself largely into a study of what are infection and immunity and how they are acquired.

Schorer defines infection as the entrance of micro-parasitic living organisms into the body tissue or substance and the occurrence of definite symptoms of disease as the result of the multiplication and action of the invading organisms.

Since infection does not always occur when pathogenic micro-organisms are present in the body tissues, it follows that certain conditions or relations are necessary to the development of a bacterial disease.

These conditions divide themselves into two classes, viz: those dependent on the biological properties of the infecting organism and those dependent upon the condition in the host or tissue invaded.

Of those conditions dependent upon the biological character of the organism those most important are the ability of the organ-

ism to multiply rapidly and the virulence of the organism or the poison it produces to some or all of the tissues of the body.

The number of organisms necessary to produce a diseased condition of the body varies with the different species; for example the innumerable saprophytic bacteria found in the different parts of the body fail to produce an infection because of their inability to produce poisonous substances in quantity sufficient to overcome the body's resistance; many staphylococci are required to produce a furuncle while a very few anthrax bacilli will cause anthrax.

Of the conditions of the host or tissue that have to do as determining factors in infection those most important are as follows:

First, the insusceptibility of certain tissue to certain invading organisms, for instance the immunity that domestic animals enjoy against venereal diseases;

Second, the mode of entrance and location of the invading organism plays an important role, for instance, the spirillum cholerae can produce its typical infection when it has entered the body through the small intestines. When introduced through the skin it produces no disease. The bacillus of tuberculosis as well as certain other organisms, on the other hand can produce their symptoms complex whether they enter the body through the skin or mucous membrane;

Third, the body fluids, lymph glands and phagocytes offer resistance to invading organisms and age, sex, race, occupation, etc., in some unknown way repel infection.

From the foregoing it is evident that any organism that produces an infection must invade the tissue susceptible to its action, multiply, produce poison and overcome the body's resistance.

The action of an organism in producing its symptoms complex varies with the specie; for example the staphylococcus produces its infection in localizing areas; the typhoid bacillus, though causing lesions in the glands of the intestines, are usually present in the blood stream, while the tetanus bacillus forms a toxin that is distributed throughout the body.

Because of this tendency of the various organisms to produce certain conditions in the tissue, the virulence of an infection is largely determined by discovering the micro-organism that produces it.

The degree of resistance offered by the host or tissue to any invading organism is measured by its sensitization to that particular organism. This sensitization is known as immunity, and is either natural or acquired. Natural immunity may be an immunity of individual or race or specie. Individual immunity may be at times more apparent than real, for instance, when the acidity of the

*Read before the Kentucky State Medical Association, Paducah.

stomach is sufficient to destroy the spirillum cholerae before it reaches the alkalined bathed epithelium of the intestines.

Acquired immunity only results when an individual has passed through either a natural or a modified course of an infection or has received substances prepared by some other individual or animal that has done so. In the first case the immunity is said to be actively acquired and in the latter case to be passively acquired.

Natural immunity is usually more persistent than acquired immunity because it is due to an insusceptibility of the tissue to the toxins while in acquired immunity the tissues are protected by the presence of immunizing bodies circulating in the body fluids and these substances are being constantly eliminated through the excretions.

Some bacteria discharge their toxins and maintain their virility and of these the toxins are said to be extra-cellular. Other bacteria discharge their toxins only upon their death and disintegration, and of these the toxins are said to be intra-cellular.

Because of these facts the immune bodies formed in the tissues when an active immunity is acquired are variously named according to their functions. Those that neutralize the extra-cellular toxins are known as anti-toxins and those that act on the invading organisms are known as anti-bacterial.

Various theories have been advanced to explain how these immune bodies are formed in the body. Klebs and Pasteur claimed that certain substances necessary as food for the immunity necessarily followed. Chauveau held that certain products in the body which protect the body tissues from further invasion by that particular parasite. Metchnikoff believed that immunity was obtained by the ability of the white blood cells and cells of certain organs of the body to engulf and destroy the invading bacteria. Salmon and Smith, Foa and Benone, Roux and Chamberlain and others observed that the products of bacterial metabolism produced immunity when injected into the tissues and held that the body tissues are chemically changed in immunization. Fodor observed that the normal body fluids and especially the blood contained substances are able to destroy bacteria.

Numerous theories by other prominent investigators have been offered to explain the observed facts, but that of Ehrlich advanced in 1897 stands out prominently. His side chain or receptor theory is an effort to explain the observed facts on a chemical basis and it is both unique and plausible. He believes that each cell of the body consists of a dominating nucleus and a number of side chains or receptors. These receptors are pri-

marily for the nourishment of the cell and secondarily for its protection. Through these receptors it has various powers of combination; for example it may anchor and assimilate food stuffs or it may combine with substances poisonous to the cell. The combination of the receptors with foods is so loose that after causing the food to undergo such changes as may be necessary for the nourishment of the cell the surplus food is discharged without injury to the receptors. On the contrary, the union of receptors with substances poisonous to the cell is so firm that they can not be separated and the cell discharges its receptors thus anchored. If the poison anchors enough of the receptors of a cell to prevent its assimilation of food the cell dies and if a sufficient number of cells which have vital functions to perform are thus destroyed death of the individual follows. On the other hand if there is not enough of the poison to destroy the life of the cell immunity results or follows.

Ehrlich assumes that when a poison fails to produce the death of a cell by anchoring a sufficient number of receptors that the cell is stimulated to the production of other receptors and this production of receptors is continued till there is an excess of receptors produced which excess is thrown off from the parent cell and constitutes what he calls an anti-body. These discharged receptors are sensitized to the bacterium or toxin that stimulated the cell to their production and constitute the body's bacterin or anti-toxin for that particular infection.

Ehrlich further assumes the cells have receptors that differ in their combining powers and he would divide these into three groups. Anti-bodies formed from receptors of the first order he says are anti-toxic, those formed from receptors of the second order he thinks are anti-bacterial, and those formed from receptors of the third order he also classes as anti-bacterial. Receptors of both the second and the third order he assumes have two combining poles and differ from each other in that the second pole of receptors of the second order enter into no combinations but exercise a catalytic influence upon the bacteria rendering them more susceptible to the action of the first pole; while the second pole of the receptors of the third class has the power of combining and anchors a ferment-like substance, which he calls complement, that enables the ambceptor to dissolve the bacteria. Thus we see that anti-bacterial bodies developed from receptors of the second order are agglutinating or precipitating, while those from receptors of the third order are lytic.

Wright and Douglas in 1903 and Newfeld and Rimpau in 1904 discovered that in ad-

dition to the anti-bacterial and antitoxic substances already mentioned that both normal and immune sera contained a third substance which the former named opsonin and the latter called bacteriotropin the action of which seems to be similar to if not identical with that assigned by Ehrlich to the second pole of his second class of receptors. The opsonic index is a measure of the potency of normal sera to dispose of bacteria or toxin and is of value as a guide in the administration of bacterins or immune sera.

Bacterin therapy, which is the administration of killed cultures of pure strain or strains of bacteria, is for the sensitization of the tissues by the development of immune bodies and the stimulation of the phagocytic action of the leukocytes (all of which Wright calls the raising of the opsonic index) and is valuable for diagnosis, as in tuberculosis, for prophylaxis, as in rabies, small-pox or typhoid fever, for the treatment of subacute or chronic conditions, as the sequelae of gonococci infection or the chronic infections of staphylococci origin.

Serum therapy is the introduction of prepared immune substances into the body tissues for the destruction of bacteria or the neutralizing of their toxins and is valuable for prophylaxis, as in diphtheria or tetanus, and for the treatment of the acute bacterial infections as in diphtheria, epidemic cerebrospinal meningitis and certain forms of dysentery.

It would unduly extend this paper and trespass upon my time limit to note the merit of the many applicants for consideration in this large and rapidly growing field of therapeutics. We shall therefore summarize the results attained by bacterin and serum therapy and leave for your discussion of the subject to develop such features as preparation of remedy, indication for use, strength of dose, reaction, interval between doses, site, preparation of site and manner of administration.

It is most gratifying to note with reference to small-pox that instead of being the scourge that it was before the days of Jenner, with a death rate of from 35 to 50 per cent, that now the mortality (thanks to vaccination) is less than 5 per cent, and including those who have been wholly protected by their vaccination the mortality is reduced to the fractional part of 1 per cent.

In ordinary cases of diphtheria most statistics show that if antitoxin is used on the first day that the mortality is practically nil; if used on the second day that the death rate is below 5 per cent; when not used before the fourth day that 20 per cent, succumb; and 50 per cent, die if antitoxin is not used at all.

In rabies the results of bacterin treatment are most gratifying. Whereas from 50 to 80 per cent, of patients bitten by rabid animals who did not have specific treatment succumbed to the disease; the mortality under bacterin treatment is only 5 per cent.

In 1903 from 4,449 Fourth of July accidents there were 406 deaths from tetanus; in 1907 from 4,413 similar accidents with the very general use of tetanus antitoxin there were but 62 deaths from this cause.

Not less remarkable are the results of bacterin treatment in typhoid fever. Maj. F. F. Russell, M. D., U. S. A., reports that observations covering a period of 18 months during vaccinated against typhoid fever were as follows: of the vaccinated there were five who had typhoid fever with no deaths; of the unvaccinated there were not thirty but 418 cases of typhoid and 32 deaths. He also says that in the English army that regiments that have less than half of their personnel protected by vaccination against typhoid are not considered properly prepared for field service.

In certain forms of dysentery, notably that type produced by Shiga's B. Dysenteriae which secretes an extra-cellular toxin, the mortality has been reduced by the use of Shiga's serum in the epidemics as they prevail in Japan from 22-26 per cent, to 9-12 per cent. Vaillard and Dopfer have collected statistics on 200 cases treated with serum with a mortality of only 2 per cent. The disease as it prevails in the U. S. and especially among children is produced by a bacillus, the toxin of which is intra-cellular and it has not been markedly influenced by serum therapy.

The treatment of meningitis, when due to diplococcus intracellularis infection, by Flexner and Jobling's serum is not old enough to warrant a statement of comparative data. Flexner and Jobling, however, have summarized the results of the treatment of 400 cases thus treated by various clinicians as follows: the period of illness is shortened, the chronic lesions are largely prevented and the percentage of mortality is markedly reduced. These observations clearly suggest that this serum is indicated as a specific therapeutic measure.

The results obtained from bacterin or serum therapy in bacillus coli, staphylococcus, streptococcus, gonococcus and pneumococcus infections have not been so brilliant as those we have just mentioned, yet in so many instances have they apparently so favorably influenced the course of their respective infections that they merit more extensive use. This is particularly true in the treatment of the sequelae or in subacute or chronic conditions produced by these infections.

Our knowledge of the nature of the antibody produced by bacterin therapy for tuber-

culosis is still indefinite. Koch, Wright and others think that it is bacterioidal while Denys, Trudeau and others hold that it is anti-toxic. Before tuberculin can be scientifically applied as a therapeutic measure it is necessary to determine the part played by the moderate reaction in the tissues and what is to be accomplished by immunization with tuberculin. As a remedial agent tuberculin is most used in the treatment of tuberculosis of joints, bones, glands, skin and urinary bladder. Thus far the most valuable use of tuberculin is as a diagnostic measure.

In incipient cases of tuberculosis, when they are not recognizable by other means, tuberculin excites a positive reaction. This vantage ground renders possible the successful combatting of the disease by hygienic, dietetic, climatic and medicinal measures, in approximately 90 per cent of cases.

Much as has been accomplished in this field of therapy, we are but upon its threshold and we confidently expect that its development will give us a specific therapeutic measure for every micro-organic infection.

In 1905 V. Pirquet and Schick originated the term serum diseases. They observed two rather definite types; one which resulted from the first injection and another which followed the second or subsequent injections. The first type manifested itself in from eight to twelve days and is largely independent of the size of the dose used. The symptoms of the first type most commonly observed are fever, exanthema (most frequently as urticaria) usually intense itching, joint pains and at times swollen and painful glands.

The second type varies somewhat with the interval between the injections. If an interval of twelve to forty days occurred between the injections the disease may develop in less than one hour; if the interval is from forty days to six months there may be an immediate reaction; if more than six months interval occurs the symptoms develop in from six to twelve days; if the injections are made at intervals of six days or less there will be no reaction of the second type. The symptoms of the second type are usually more acute and general than those of the first type. Gay and Southard in 1907 observed a substance in horse serum which they called anaphylactine. They think that its action accounted for the sudden death of guinea pigs sensitized to horse serum. While anaphylactine has not been found in the blood serum of man, later investigations may show that the phenomena of serum disease in man corresponds to anaphylaxis in guinea pigs.

Roseman and Anderson think that the essential lesion of serum anaphylaxis is located in the respiratory centers. Several cases of sudden death following the injection of anti-

toxin into asthmatics have been reported. Knowledge of the fact that injection of horse serum into asthmatics may be attended with danger should be considered in the use of anti-toxin. Fortunately the percentage of persons in whom serum anaphylaxis occurs is so small that it is far outweighed by the beneficial results of injections of specific immune sera in the prevention and cure of certain diseases. It is to be observed, however, that the use of bacterins and sera are not without danger and they should not be administered without positive indications. The same observation may be made regarding many of the drugs in common use and bacterins and sera should be administered with the same knowledge and discrimination as are the other remedial agents of our pharmacopoeia.

In conclusion we feel warranted in drawing the following inferences as representing the present thought on this subject.

First, the cells of the body tissue are subject to the same chemical laws that govern other substances and their differing powers of forming combinations are dependent on their functions in the animal economy.

Second, that the body fluids contain certain substances, the product of cell activity, for the defense of the body and that the presence of these substances in the body in relative quantity and in an uncombined state determines the susceptibility of the body to infection.

Third, that bacterin therapy stimulates this cell activity against its particular infection and is useful for prophylaxis and for the treatment of subacute and chronic infections.

Fourth, that immune sera contains prepared substances that neutralize the toxin or destroy the bacteria or do both and are useful for prophylaxis and for the treatment of acute infections.

Fifth, that the opsonic index together with the clinical symptoms should be our guide in the administration of bacterins or sera.

DISCUSSION

C. G. Daugherty, Paris: With reference to the newer method of treatment of diseases by hypodermatic medication, I am sorry that all of the papers in the symposium were not presented.

Some years ago during a visit which Dr. C. A. L. Reed made to Italy, his attention was called to the fact that a large number of diseases could be treated by means of various medications or medicine given by the hypodermatic method. My own personal experience has been limited to iron and arsenic, the citrate of iron and the arsenite of soda, cacodylate of soda, bichloride of mercury, and gray oil in one of the newer forms.

I wish to ask Dr. Pope, who has so kindly filled the requirements of the program, in giving the treatment of disease by means of iron and

arsenic, atoxyl, and so forth, if in his experience he has had nausea following the administration of iron and arsenic. At first, we thought it was the psychic effect, but almost all of the patients have had some sensation of stimulation or of nausea if they did not lie down, and in some cases it resulted in losing a meal, and that is just the time when the meal is not to be lost. My experience has been that the results from the use of iron and arsenic, or of iron alone, have been most gratifying in cases of severe anemia or the type of chlorosis, and in gastric ulcers in which we have severe anemia and that peculiar condition of the stomach accompanied by hemorrhage, known as gastrotaxis the iron making up one per cent, hemoglobin per day, with iron on alternate days one half per cent. The results were gratifying. As Dr. Pope has pointed out, when we attempt to treat anemic patients by means of the administration of iron by the stomach, their digestion was severely taxed to take care of the iron. These preparations seem to stimulate the hematopoietic organs in cases of other diseases, such as tuberculosis, etc.

I had a case which I suspected was tuberculosis. The patient had a fistula in ano and various other conditions. Nutrition was very much impaired, but I found I could not build that patient up in any other way than by hypodermatic medication of iron and arsenic.

Dr. Pope alluded to atoxyl and condemned its use, speaking of its administration in large doses the same as in cases of syphilis and sleeping-sickness. The dosage is so small for pernicious anemia that you will be gratified to know that according to Allen Starr, seventy-five per cent. of the cases are curable by it, and if you come across some cases of pernicious anaemia in which you have almost the symptoms of locomotor ataxia, with loss of the patellar tendon reflexes and cord symptoms, or in a case of multiple neuritis in which you have the toxic effect producing even pernicious anaemia, it is gratifying to think we have a remedy which may cure seventy-five per cent. of the cases.

With regard to the administration of mercury hypodermatically in the severe cases of syphilis—I do not refer to the cases in which results can be obtained from the use of salvarsan, but those in which we have given "606" and have cerebral luetic symptoms—the bichloride, in 1-4 grain doses, bi-weekly, 10-15 doses, gives us the quickest results in relieving the cerebral symptoms. Later on, we can follow it by the administration of mercury, and for that purpose from the use of Heidsieck's method of gray oil mixture—mercury, dental bi-distilled, unsterilized English lanolin, camphoric acid, and beechwood creosote—my results have been gratifying in the treatment of these cases, in addition to salvarsan by the intravenous method, and I commend to you an article by Dr. Eugene Carson Hay, of Hot Springs, Arkansas, in which he reviews the whole

question of mercurial administration. The results obtained are so gratifying that we certainly have at our command a valuable means of treating cases where we do not wish to use salvarsan, or when we wish to use it in addition to other remedies. The number of cases of locomotor ataxia and of late forms of luetic infection seem to be so common that I do not believe we can afford to treat any case of luës without resorting to the hypodermatic administration of mercury. Again, there are so many cases of so-called malignant disease, such as epithelioma, that yield to the hypodermatic administration of mercury, that I commend this article of Dr. Hay to you, which can be easily had.

With regard to the other forms of hypodermatic administration of medicines, the salicylate of soda is being given, and an article by Dr. Alexander Lambert in a recent issue of the Journal of the American Medical Association takes that up in a way that will cover the symposium to our satisfaction.

With regard to bacterins, I wish to ask those who have been investigating them whether in immunizing children they give the full dose of five hundred millions for the first day and a billion in ten days, and a billion ten days after that. It would seem to me from the manner in which they administer the bacterins, to avoid a negative phase, we should divide the dose in half for children. In a recent epidemic of typhoid fever in my native city, Paris, the infection having been caused by drinking spring water, several children to whom I administered a dose of five hundred millions seemed to have had a pronounced negative phase, which, however, produced no bad results and has resulted in immunizing all to whom I gave the three period treatment.

Virgil E. Simpson, Louisville: That iron during the prolonged course of administration will frequently result in deranging the gastro-intestinal functions is a well known fact; that this result is often brought about because of improper dosage seems not so well appreciated by members of the medical profession.

I recall very vividly that during my course in medical school I was afflicted with varioloid. Being a medical student I was promptly sent to the eruptive hospital, and during the progress of the varioloid I developed facial erysipelas. I was isolated still further in what is known as the yellow fever ward, and the man in charge of the institution on his first visit, after the erysipelatous development, gave instructions to the attendant to have administered to me tincture of chlorid of iron in teaspoonful doses every two hours! Suffice to say, within a short time after this dosage was begun my stomach went into a state of rebellion, and if the iron had been of real service in controlling that attack of erysipelas, which I question, the doctor would have defeated the object he had in mind by putting the stomach in such a condition that it was impossible for me to

further absorb any of the iron. When we remember that in health when the physiological processes are being performed undisturbed, that there is less than one quarter of one grain of iron eliminated from the human body in twenty-four hours, we can readily appreciate it is preposterous to administer such large and heroic doses of iron as we sometimes see given by physicians.

If more iron be given than is necessary to maintain the iron equilibrium much the greater part of the excess is eliminated by the intestinal canal in the form of sulphides and tannates; a small part of the excess may be absorbed and even stored up in the liver and bone marrow but is eventually eliminated by the caecum and colon chiefly. It is quite true that in anemias there is an iron hunger and when given as a drug more will be absorbed until the normal equilibrium is established, but it is scarcely reasonable to assume that such large quantities can be cared for.

There has long been a discussion as to just how inorganic iron produces the effects that, clinically, we know result from its administration. One school, headed by Bunge, contended that food-iron, which is organic iron, is so combined that it is not easily dissociated by the sulphides in the bowel, hence almost all of it is absorbed; that in anemias, eg. chlorosis, large amounts of sulphides are found in the intestine and more, or all, of the food-iron is converted into ferric sulphid and absorption made impossible; that inorganic iron when given in these conditions, forms sulphids with substances in the bowel thus satisfying the chemical attractions and leaving the food-iron free to be absorbed. In other words, inorganic iron is never absorbed by the intestinal epithelium. The other school has by modern pharmacological methods, established these facts which convert Bunge's theory; that if inorganic iron merely acted by combining with the H_2S in the bowel, certain other drugs would be just as effective in anemias as iron; that sulphid of iron may be given as a therapeutic agent and improvement follow; finally, that iron given hypodermatically is curative in these conditions just as certainly as if given per os. In other words, it is a fact that iron in any form is absorbed, and, if properly given either by mouth or hypodermatically, will produce clinical results whenever iron is indicated. When given per os all forms of iron are converted into the chloride in the stomach, pass into the intestine to be changed into albuminates and as such absorbed. After absorption iron undoubtedly undergoes further syntheses in the liver, spleen and other organs and tissues.

I would urge in the administration of the iron preparations, whether by mouth or hypodermatically, that there go along with that administration the systematic examination of the blood of the patient. It is a procedure that is easily carried out. Any doctor can procure, if nothing else, Colquist's hemoglobin scale, and with ap-

proximate accuracy in a few seconds can determine the hemoglobin percentage changes in his patient. Those who are supplied with microscopes and possess the technic to make an estimation of the red and white blood cells and the relative proportions of the varieties of the latter, will not be content with the mere hemoglobin estimate infinitely better than no examination though it is.

The administration of iron, as I alluded to in the beginning, I believe, defeats the very purpose we seek so frequently when administering it by the mouth because of improper dosage. When we administer it hypodermatically we are more careful about the total amount of iron injected. We secure, in addition to this, a more complete observation and control of the patient while coming to the office for the hypodermatic administration. If we were to write a prescription for iron to be taken per os, we would probably not see the patient before two or three weeks have elapsed, and we are unable during this interval to control with any degree of nicety the total amount of intake of iron at any particular time. If these patients are being administered iron by the hypodermatic method, we then have them under immediate observation, and it is much less difficult to control the patient with reference to other suggestions we would like to make as well as observe the immediate effect of the drug we are giving.

B. J. O'Connor, Louisville: There are a few points in connection with the subject of serum and vaccines which need to be emphasized. The essayist did not emphasize the importance of making a clear distinction between a serum and a vaccine. Not infrequently I have heard physicians speak of a serum when they meant a vaccine or a bacterin. A very clear distinction should be made between the two. The difference in the administration of the two is so great that a man commits a grave blunder when he uses the terms serum and vaccine synonymously or interchangeably, or when he prescribes one for the other. In the administration of a vaccine there must be a period for a reaction between the doses, whereas in the case of a serum you can give it repeatedly.

In connection with serum sickness or anaphylaxis brought out by Dr. von Pirquet, serum sickness occurs a great many times after the primary injection of the antitoxin, but the more dangerous point is the secondary injection that is given after an interval of two weeks or up to six months after a primary injection. For that reason, all of the modern observers agree that the use of antitoxin as a prophylactic in diphtheria is not indicated; that it is dangerous to use it, because if you do, and must use it in a case of diphtheria occurring shortly afterwards in the same patient, you are likely to produce a serum sickness which may prove fatal. The mortality

from the secondary use of serum sickness is not small.

Another point is in regard to the use of serum for tetanus. While the doctor mentioned Fourth of July injuries from blank cartridges, etc., it is well to use the anti-tetanic serum as a prophylactic measure in street injuries, where the street dirt is ground into the wounds, and in punctured wounds about stables, and if you would prevent tetanus from developing in these cases you should use the tetanus antitoxin at the time of the injury. You should not wait for symptoms.

The Flexner serum is unquestionably one of the greatest advances in the treatment of cerebrospinal meningitis we have. The doctor did not emphasize the importance of the early use of Flexner's serum. Of course, the Flexner serum would have no influence in streptococcal meningitis or tubercular meningitis, but when we are dealing with meningo-coccal meningitis, if the serum is used early enough, and in accordance with the technique Flexner has given, the results are certain to be good.

One word about the use of bacterins. Bacterins must be handled by one who is more or less experienced.

It is not necessary to rely upon the opsonic index as a guide to vaccine therapy, but close observation of the temperature, of the increase in the discharge, etc., is necessary. Autogenous vaccines are unquestionably a great deal more reliable than the stock vaccines. You cannot tell when you have a case of acne whether you are dealing with a plain staphylococcus or pure acne infection or with the acne bacillus and staphylococcus. You may have two or three types of staphylococci there, and the autogenous vaccines are more reliable. The acne bacillus is an anaerobic organism. A great many mistakes are made in giving the autogenous vaccines too early. Small doses can be given early, while larger doses require a longer interval.

Great use may be made of typhoid vaccines, not only as a prophylactic measure, but also as therapeutic agents. If you use small doses of typhoid vaccine in the early stages of typhoid fever, you will reduce the mortality one-half. Many observers have demonstrated this beyond the shadow of a doubt.

I had one case in which Dr. South made several Widal examinations, but in the early stages the Widal was negative. After the administration of the first dose of typhoid vaccine there was no reaction. The second dose acted almost specifically; the temperature went down immediately, every symptom cleared up within four days, and the patient went on to an uninterrupted convalescence. Another patient recently treated with typhoid vaccines reacted promptly, the febrile symptoms completely disappearing within a week after the first injection. In this instance three injections were given, the first of 50,000,000 bacilli,

three days later a second of 75,000,000, and several days later one of 125,000,000.

Vernon Blythe, Paducah: We have been so flooded with literature upon serum and bacterins that it is a difficult proposition sometimes for doctors in small towns and small cities to really get the truth of just what the meaning of all this is.

The real scientific observation of sera to a great extent began with the number of infections that occurred at Chickamauga Park during the Spanish-American War, when the army was in camp there, and there was a terrible mortality from typhoid fever. With most of the literature we have had coming from the firms that have prepared these vaccines, such as Mulford & Company, Parke Davis & Co., and others, it has been difficult to get at really careful and concise observations along this line; but there are a few things I have noticed in my use and experience with them. One is the use of pneumostaphylococcal bacterins. I have observed that in the study of pneumonia, where there is great difficulty in overcoming the conditions that follow, where there is a remaining pneumococcal condition in the lungs, where there is the formation of staphylococcal infection and streptococcal infection, that injections of small doses of the mixed bacterins have been very efficient. But there is one thing I have also noted, namely, that you have to handle these bacterins with great care, otherwise you will get a negative reaction. If this is not done, you will do more harm than good. I have had some patients who have had considerable diarrhea after the use of these bacterins. I usually start with twenty-five million, thirty-seven and a half million, fifty million, working up to seventy-five million or to one hundred and one hundred and fifty million. I have rarely found it necessary to run over fifty million in the use of the mixed bacterin. If you do not give them with gradual steps the symptoms become worse. I have had patients with severe diarrhoea resulting from their administration. After close observation I have not found that the diarrhoea was due to dieting or to the food these patients took; that it was due to a reaction from the serum, or rather the bacterins that were administered.

With reference to the use of bacterins in the treatment of gonorrhoea, I think they are absolutely useless in the first stage. It is only in the old cases that we get results, but I do think in arthritis, or even if there is no arthritis, if there is long continued case of gleet, that they have a marked and wonderful influence. I think that these facts should be brought to the attention of doctors in small towns just as well as to the men who live in the large centers of population. It is remarkable that we have at hand in the course of ten or fifteen years a vehicle by which thousands of lives can be saved, and yet the practical value of which is so little appreciated

and the sensible handling of these bacterins so little understood.

With reference to vaccines in connection with typhoid fever, as we all know, according to recent experience in the army of the United States while in camp upon the Rio Grande, these vaccines have proven to be a vehicle of great importance in protecting men who were exposed to typhoid infection. With reference to the use of tuberculin, with the little experience that I have had with it, it seems to be very efficient and striking in its results, but it should be handled with the greatest care and with the most astute judgment when we use it in tuberculous subjects.

L. H. South, Bowling Green: I would like to say a few words with reference to the treatment of hydrophobia. When a dog has bitten a person on an exposed surface, like the face or hand, the treatment should be begun early, and I am pleased to announce that the State Board of Health has made arrangements with the Hygienic laboratory at Washington to supply us with the cord of this treatment, so that we can give it free to patients; but they must come to the laboratory. That is one of the requirements of the government. However, if any family physician wishes to give this treatment, this virus can be secured from the various laboratories, like Parke, Davis & Co., Alexander & Co., at the moderate cost of fifty dollars. The laboratory will be glad at any time to make an analysis of a dog's head and treat these cases. Positive results have been secured in a great many of them. It requires twenty-five injections, and each patient has to be at the laboratory from twenty-one to twenty-five days.

Curran Pope, Louisville: I want to answer Dr. Daugherty's question by saying the average dose given hypodermatically is from five centimeters to one decigram. In giving his remedies, if he will draw the entire contents of the ampule into the barrel of the hypodermatic syringe, and then administer the first dose, as I suggested, one-third of the dose the first time, he will get one-third of a centigram, and the next time you will get 0.30, and the next time .5, and by the fourth or fifth dose he will get the full dosage of the larger ampule. That has been the way in which I have started, and I have done that not only with the iron, but with the arsenic. My experience has been that patients are more susceptible to a sudden introduction of the larger dosage of arsenic than they are to the larger dosage of iron. I have never had any serious attacks of nausea in that way, nor have I had any unpleasant sequelae following the administration, and I attribute this to the fact that I adopt this principle in the medication of nearly all patients that come before me. I realize this fact, no matter how well you or I may know disease and may intelligently comprehend and interpret the clinical fact of that disease before us, namely, the patient, yet there is always a phase we cannot

know and it is impossible to know, and that is, how that individual is going to react to the medication. That patient at the start, speaking in the nature of mathematics, is the unknown quantity X, so that our administration of the iron should be a small dose at the start if the iron plus X, the unknown quantity, in the clinical case demands a very small dose at the start. I do that with every case that comes before me. If I had to take four or five days longer to build up that case to a certain dosage, I have done better than running the risk of taking F. E. or A and giving him the maximum dose. It is simple to my mind. It is a matter of little mixing. Sir Joshua Reynolds was once asked how he was able to paint with such wonderfully fresh paints, and whether there was any particular thing he used in mixing the ingredients. He replied that all he had to do was to take his pigments and mix a little brains with them. (Laughter). It is a good hard, rough, commonsense proposition to take the unknown quantity X in a patient and add a little cerebral tissue to that and start with a small dose and build up, and that is the reason I believe I have had no ill effects from the hypodermatic administration of medicine.

Another point with regard to the use of vaccines. I have had a very limited use of these vaccines, and from what I have seen of them and with other physicians, I have been led to the conclusion regarding one form of bacteria that I think is interesting enough to know, and that is this, that the ordinary stock vaccines are very good in average conditions until we come to the colon bacillus. My observation has been that there is absolutely no stock vaccine that is so unreliable from the standpoint of the clinician as the colon bacillus vaccine. It is in these cases I think we shoot in the dark. If we are lucky enough to get in the bacterin the particular colon germ causing the trouble, all right. If you have missed the target, you are all wrong. For that reason, I have ceased using them in such cases as come before me, and, gentlemen, I will say, those of you who have had to deal, for example, with a parietic bladder of the ataxic, can realize what it means to have a colon vaccine at hand and the immense amount of good that will come from it. It is simple if you can have an autogenous vaccine made and use it, but I find it is a waste of time to be shooting around with one preparation and then another as we have been doing in the past. You will find some of these things very effective.

C. E. Purcell, Paducah: There should be definite and positive indications for the administration of the serums and bacterins and all must have recourse to the laboratory and the cooperation of the bacteriologist if we hope and expect to meet these indications scientifically. I have had very little personal experience with the bacterins, and therefore I shall limit these remarks to the serums. Ever since it has been

known that we can produce, artificially, in animals, the condition of anaphylaxis, by the hypodermic introduction of certain substances and that this condition exists in man, in some cases physiologically, and that a prophylactic dose of serum might therefore sensitize a patient and render a therapeutic dose dangerous or even fatal, I have always believed doses of serums unwise and the risk unwarranted. Having the utmost faith in the antidiphtheritic serum and knowing that every child or person exposed to diphtheria will not contract it, I prefer to wait till conditions develop sufficiently to warrant the use of antitoxin. You will note I use the term conditions where ordinarily we would expect to use "symptoms." I do not believe antitoxin should be given on phenomena alone unless they are very positive and the physician far removed from a competent bacteriologist. I feel certain in my own mind, that we should not be too hasty in giving antitoxin in cities where skilled assistance from the laboratory can be had. Many sore throats with simple ulcers and streptococcal membranes are diagnosed diphtheria and treated with antitoxin. I doubt very much if there is a clinician who does throat work exclusively, who sees a large number of cases and who on objective symptoms alone can differentiate positively in every instance between a streptococcal membrane and a diphtheritic membrane.

I am certain now, since depending more on laboratory tests that I have given antitoxin in ulcerative tonsillitis and streptococcal membranes. Fortunately, however, I have had no bad results from such administration, though I have talked with men who would not under any conditions give antitoxin because of deaths they had witnessed following immediately the injection of the serum. If we will have every membrane formation from the throat and larynx subjected to laboratory tests we shall soon find out how often we are mistaken in our clinical diagnosis. A membranous formation in the larynx is usually diphtheritic; a simple laryngitis with a husky voice requires no serum. We should not be too hasty in giving the serums.

Aside from the certainty of each diagnosis and the consequent employment of positive therapies, there is the patient's side and the family's interest to consider. From the patient's standpoint it is far better to secure a bacteriological report, and not call the case a suspicious one and advise antitoxin to be on the safe side, than to buy serum at present prices and be subjected to the disadvantages and losses of quarantine and fumigation and the necessary expense of reopening the house, when no diphtheritic bacilli are found.

Try immersion in hot water baths for indolent bedsores and large, slowly healing burns. You will be surprised how grateful such treatment is and how often it is highly advantageous.

IMPORTANCE OF EARLY DIAGNOSIS IN MALIGNANT DISEASE.*

By WILLIAM H. WATSEN, Louisville.

I did not expect to be called upon to discuss this question, and I will have to do so orally as I have nothing written.

Any surgeon who has had an extended experience in operating for malignant disease will have appreciated the great importance of early diagnosis. We make a reasonably early diagnosis in cancer situated in certain parts of the body, while in cancer situated in other parts we make a very late diagnosis—too late in many instances to do any good by a surgical operation. Let us take cancer of the uterus in which I have had a very broad experience extending over thirty years. In looking back over the numerous cases I have operated upon, and the many others upon whom I have not operated, I should say that from eighty to ninety per cent. have been referred to me, or have consulted me of their own accord, when it was too late for any hope for a permanent cure by operative procedure. The only hope from operation at that late period is to afford temporary relief, and the prolongation of life, sometimes from six months to one year. This delay is due to two or three reasons. In the first place, our women have not been taught the significance of the symptoms of cancer of the uterus. This is mainly due to the medical profession, and I must say that it is very largely ascribable to the failure of our teachers in medical colleges. We have not in the past emphasized sufficiently the importance of early diagnosis in uterine cancer. We have not taught all the methods and means of making early diagnosis. I fear we have talked too much to our students about the operative procedures at the expense of the important question of diagnosis. We should not only teach in cancer of the uterus but in many other diseases careful diagnosis, and let the surgical procedure come later, even after the graduation of the student, and when he can gain experience in a hospital.

In Germany they are doing much better than we are and the percentage of late cases, the inoperable cases of uterine cancer, is not fifty per cent. of the number or percentage we have in this country. They have educated their physicians in this particular better than we have, and they have educated their women. If we would educate ourselves carefully as to the means of diagnosis of cancer of the uterus, and then if we would interest some of our strong-minded women who are able to lecture to large audiences of their lady friends,

*Read before the Kentucky State Medical Association, Paducah.

very soon nearly all intelligent women would learn the symptoms that would indicate the necessity of being examined. Women should be taught that after the age of forty the ratio of cancer cases increases rapidly. They should be taught the importance of irregular hemorrhages between the menstrual flow, continuing for any considerable time, or the importance of a hemorrhage continuing after coitus, with often a leucorrheal discharge, watery in character, sometimes a little offensive; or the importance of being examined when they have passed the change of life and have hemorrhages with an offensive discharge. And these symptoms, without enumerating others, are sufficient to indicate the necessity for an examination.

The physician should be trained how to make an examination. If the cancer has advanced very far a digital examination will often tell an experienced physician or surgeon the nature of the disease; then he may examine with the speculum the cervix, and if he is not still satisfied he may make a section from the cervix and submit it to a trained pathologist for examination; or if there is no trouble in the vaginal cervix he may have a thorough curettage made, removing tissue from every part of the endometrium, because if this is not done he may miss the very point where the cancer is situated. The disease may be very small or circumscribed. It may involve but little of the endometrium. The material removed can be preserved in a 10 per cent. formalin solution and submitted to the pathologist for examination. When I say a pathologist, I mean one who is thoroughly trained in making these examinations. All this can be done because there is always in this country not far from any physician a well trained pathologist to whom the specimen can be sent preserved in formalin solution.

It is a sad commentary upon the intelligence of womanhood that when we recognize mammary cancer most of the cases in this country have gone too far for any hope of permanent relief before a physician or surgeon is consulted. While the percentage is much lower than in cancer of the uterus, it is five times as high as it ought to be if women were taught to consult a physician whenever they find a lump in the breast. I have known women, however, to consult no physician for probably a year or a year and a half after they found a large lump in the breast. By this time the disease has gone too far for surgery to offer much permanent relief. Again, we see women with a lump in the breast as large as an average orange accidentally discovered, showing that they do not study the condition of their breasts carefully.

We now come to cancer of the gastro-in-

testinal tract which in a surgical sense is attracting the attention of surgeons everywhere. Nearly all cases of cancer of the stomach are operated upon when it is too late to offer much hope, the mortality being high and the return of the disease being rapid. This is because we have been waiting too long for stomach analyses and test meals to diagnose the case. While stomach analyses should not be in any sense condemned but encouraged, if we depend solely upon stomach analyses to make a diagnosis of cancer of the stomach—I mean an operable diagnosis—then the diagnosis is of no account because the patient's disease will be too far advanced to derive any benefit from operation. If we expect to get good results from surgical interference in cancer of the stomach, we must operate in what we do now consider the pre-cancerous stage or in the early stage of the cancer. When I make that statement, you may say that I am asking you to operate when there is no necessity for it, but, gentlemen, every case of cancer, with the fewest exceptions, has a history of pathology in the stomach that requires an operation, let it be cancer, or let it be chronic ulcer of the stomach or of the duodenum. You should relieve that pathology, and the operation then is a comparatively simple one. If you are suspicious when you enter the cavity from the microscopical appearance that the disease is malignant, always do a thorough resection of the stomach, go well out in the healthy tissues and remove all of the diseased structure, and in this way you will get reasonably good results.

In from sixty to seventy per cent. or may finally be ninety per cent. of the cases of cancer of the stomach the disease develops in the site of the scar of an old ulcer. Moynihan and Mayo and others, who have done so much of this work, find from sixty to seventy per cent. of the patients have a recurrence after the disease has been removed. Fortunately, we do not often have primary cancer in the duodenum; but if the duodenum is the organ that is involved in calloused ulcer we make a gastro-jejunostomy, and probably also a resection of the scar in the duodenum.

We probably seldom or never have cancer of any part of the small intestine, (fourteen cases in the *Rochester Clinic*) the disease being nearly always confined to the stomach and large bowel. In the large bowel we find cancer most frequently in the sigmoid flexure. We find it next in frequency in the ileo-colic juncture and the ascending colon, but not so often in the transverse colon. According to Mayo's statistics, published in the papers from Rochester, recently issued, the last volume, in thirty-two cases the disease occurred in the sigmoid flexure and descending colon; the ileo-cecal

juncture and ascending colon in twenty-eight and in the transverse colon in nine.

What should we do with reference to diagnosing these cases of cancer of the large bowel? While the diagnosis cannot always be made in the early stages, there are, as a rule, sufficient symptoms to indicate the advisability of making a laparotomy, and then you can make your diagnosis by the sense of touch and the sense of sight.

What has been the result of operative procedures in the past upon resection of the bowel? They have not been good because of delay, but we are doing much better now, and if we would operate more promptly, nearly every one of them would recover from the primary operation and many of them would remain permanently well. If you make a timely operation, there is no part of the human body in which you could do more successful work, probably the most successful, and the work is not difficult, and the bad symptoms following operation are surprisingly few. In resecting the large bowel for cancer, where I have made a lateral anastomosis, there has been practically no more distension of the abdomen following the operation than is usual after an ordinary laparotomy. The gas and fecal matter pass freely through the anastomotic opening; but if we delay operating on these cases until the adjacent structures are involved and the patient is much emaciated, then we will have bad results just as we would in delayed cancer in any other part of the body.

Let me impress upon you the great importance in any form of cancer in any part of the body, whether it be the uterus or abdominal structures, etc., of early operation, and insist upon teaching the people the necessity of consulting a physician when symptoms referable to these organs or structures are manifested.

IMPORTANCE OF EARLY DIAGNOSIS IN MALIGNANCY.*

By A. L. THOMPSON, Madisonville.

Of the many diseases with which the human race is afflicted there is not one whose direct cause is more mysterious, whose onset, as a rule, more insidious and whose prognosis, in neglected cases, more grave than that of malignancy. It might be compared to a thief, who does his work under the cover of darkness. If perchance he gains entrance to the house, while his unsuspecting victim yet sleeps, and arranges all details of his robbery without arousing him, he is master of the situation. Just so is the thief, cancer, who seeks

the life of its victim, master of the situation if the individual is not awakened to the significance of the early signs of the disease, that the proper steps might be taken to have it completely eradicated.

There is no other disease which is productive of more loathsomeness, mental anguish, hopelessness and misery than that of cancer. Who can imagine a more pathetic sight than that of a poor woman, in the very clutches of death as a result of cancer of the uterus, who had perhaps long since consulted her physician for relief from unnatural uterine hemorrhages, and who, on account of the profound ignorance or unjustified carelessness of the physician, was assured that her condition was nothing more than the "change of life," and turned away with some simple prescription, to battle with this monster, in darkness, until the golden opportunity for recovery slips by; then, as a last resort, she appeals to the surgeon for relief, only to be informed that her condition is one of malignancy and so far advanced that nothing short of death can relieve her.

A review of the literature reveals the fact that, while there has been a most gratifying decrease in the death rate from the infectious diseases, there has been a marked increase in the mortality from malignant disease, some authorities estimating it at more than four times greater than it was fifty years ago. Such a great increase, however, might be due, to some extent, to the perfected methods of diagnosis, enabling physicians to recognize cancer where formerly death would have been attributed to some other cause. But could it not be said with equal propriety that many deaths formerly attributed to cancer would now be recognized as other diseases? Be that as it may, despite the fact that clinicians are putting forth great efforts in perfecting the means of diagnosis, and surgeons are widening the field of operative interference and improving the technique of operations, statistics seem to indicate a continued high mortality rate from this disease.

Cancer is on the increase, and it frequently occurs under the so-called cancer period. Several cases are on record which were observed in individuals under ten years of age. It is a world-wide disease and is one of the greatest problems with which we are confronted to-day. The death rate from this disease is second to none, excepting tuberculosis, and it is rapidly approaching this in numbers. In England it is estimated that of those individuals over thirty-five years of age, one out of every eleven men and one out of every eight women die of cancer. In Germany, in 1879, there were 6,330 deaths from cancer, in hospitals; in 1889 the number had increased to 24,000, and now it is estimated at 40,000 a

*read before the Kentucky State Medical Association, Paducah.

year. In New Jersey, in 1900, there were more deaths from cancer than from tuberculosis, and in New York State, in 1907, there were more than half as many deaths from cancer as there were from tuberculosis. It is said that there are \$25,000 deaths a year, from cancer, in Japan, while in this country, with 80,000 cases constantly in progress, there are 40,000 deaths a year.

The problem of tuberculosis has been solved, and to-day through the united efforts of the profession and laity the disease is being gradually controlled and the death rate is yearly being lessened. This is also true of other diseases. Even the hook-worm has succeeded in creating great consternation among, and exciting the enmity of, the public, and, as a result thereof, the profession, philanthropist and laity have put their heads together and measures have been adopted whereby this little animal is being eradicated. Thousands and thousands of cases are being treated and cured each year, with the result that individuals affected with this disease are translated from a state of mental and physical depression, slothfulness and uselessness to one of activity, and are thereby made happy and useful citizens. Not so with cancer, a disease entailing so much torture to the patients and such expense to those to whom they must look for support. While there are thousands of cases constantly under treatment, the permanent cures can not be numbered by the thousands, and this is due to the fact that many thousands of cases come to the surgeon too late, because of the inability of physicians to make early diagnosis. Pathology teaches us that cancer is a limited local disease in its beginning and that it can be cured if the entire area involved is removed. It is obvious, then, that an early diagnosis is an essential fundamental in the reduction of the mortality rate in this disease.

The cancer question needs our interest fully as much as does tuberculosis or any other malady with which the human race is afflicted; and until the profession is fully awakened, and succeeds in awakening the public, to the gravity of the situation, we may justly expect a continued high death rate in this disease. Each and every physician should consider it his profound duty, and indeed it is, to endeavor to impress on the mind of every patient, who consults him as a result of some obscure condition, the possibility of malignancy and the great importance of an early diagnosis of this condition, inasmuch as therein lies the only hope of a cure. If the proper interest be manifested in these patients, and they are impressed with the fact that we have their welfare at heart, we shall experience little difficulty in gaining their co-operation in an endeavor to determine the nature of the

existing condition; and in every suspicious case that comes under the observation of a physician, he has not performed his full duty until every known means of diagnosis at his command has been utilized. There is much that can be done that is often left undone. For instance, if the case be one of some disturbance of the function of the stomach, much valuable information can be gained by an examination of the contents, and this should be done in every case presenting marked or persistent symptoms, especially in individuals past the age of thirty-five. Yet how many physicians do we find who do this work? I am convinced that the number is relatively small.

We should be liberal in disseminating what knowledge we have of cancer, to the public, so far as early signs are concerned. Every woman should be instructed to seek the advice of a competent physician immediately upon the discovery of a mass or an unusual change or sensation in the breast, and the people at large should be impressed with the importance of an early inspection, by a physician, of any small ulcer, area of hardness in the lips or tongue, or any tumor formation, no matter how small or insignificant, and all such abnormalities should be considered malignant unless it can be positively verified that they are not. Such a statement might be tinged with pessimism, but an optimism that is productive of so much torture and so many premature deaths should not be entertained. Accumulated evidence has shown that it is dangerous to trifle with these apparently harmless tumors. I believe that it would be a wise thing for physicians to advise the removal of any and all tumors, be they nothing more than simple warts, for they can be of no possible benefit to an individual, they can be easily and painlessly removed, and that without danger, if they are external and small tumors, and there is always a possibility of a resulting malignancy if they are neglected. It should also be borne in mind that trauma is sometimes productive of sarcoma. Those cases accompanied by fracture, dislocation, great laceration, or injury to important vessels or nerves demand constant attention and are frequently inspected by the medical attendant; but in those cases with an absence of laceration and with little swelling, no more attention is given than the comfort of the patients demand, and in just such cases sarcoma sometimes develops. This, of course, is relatively rare, but the fact that it does occur should be a strong incentive to physicians to be on the alert in these cases, and individuals receiving such injuries should be informed of this fact and admonished to return for examination at the very first appearance of

any unusual pain or swelling in the region of the injury.

As a rule, it is a comparatively easy matter to make an early diagnosis of malignancy in accessible organs, if one will take the pains to send a specimen of the diseased tissue to a skilled pathologist for examination. In inaccessible organs we have a different proposition with which to deal, an early diagnosis often, if not always, being impossible. But a realization of this fact does not justify us in a failure to perform our full duty; but on the other hand it should make us more determined in our efforts, and more alert and painstaking in our examinations. We should watch for new and early signs of the disease in all suspicious and obscure cases and make a careful note of our observations. Who could not readily make a diagnosis of carcinoma of the stomach after it has proceeded to such a degree as to produce the so-called coffee-ground vomitus, cachexia, palpable mass in the epigastric region, etc? But what has been accomplished when such a diagnosis is made? Better for the patient that he remain in ignorance as to the nature of his illness, as a cure is impossible after this stage of the disease is reached. It has been wisely said that the easier the diagnosis in this disease, as a rule, the greater the prognosis.

Humanity is looking to the medical profession for a solution of this great problem. It is a great debt that we owe, and each individual that dies of cancer is but a statement sent us, by the public, of what we are due it. Hence, there should be united and untiring efforts on the part of the general practitioner the surgeon, the pathologist, bacteriologist and biochemist in an endeavor to arrive at an early solution of the problem; and in the meantime such measures as will arouse the public to a proper conception and appreciation of the situation, and encourage philanthropists to contribute more liberally to this cause, should be instituted. The public stands ready and eager to lend a helping hand in dealing with such problems, as has been demonstrated in the great fights against tuberculosis, yellow fever, hook-worm disease, etc. But in this matter, as in all other matters pertaining to public health, the medical profession must take the initiative, and must disseminate at least a part of its knowledge to the public. No sane and conservative business man would consider for a moment the displaying of his goods before a circle of business men, only. The outcome of such a policy is obvious to any one. To make a success in the business world, one must put his goods before the public and impress the people with the fact that he has something worthy of their consideration. Just so it is with the medical profession to a certain extent, in

dealing with these great problems. If we are to succeed in combating cancer we must make it a public issue, and let it be known that it is a matter of vital importance to every one. The true cause of cancer might be discovered in the near future, but until a specific is discovered for it, we are to remain in a more or less helpless situation, so far as a cure is concerned. The only hope in view lies in early diagnoses, with early and complete removal of the diseased areas; and this can be enhanced materially by a wide-spread educational campaign along this line.

IMPORTANCE OF EARLY DIAGNOSIS OF INTESTINAL OBSTRUCTION.*

By P. C. LAYNE, Ashland.

It appears to the writer that the burden of this symposium has fallen upon shoulders far too feeble to support its onerous weight. There are several reasons for this belief: 1st. The very name of intestinal obstruction has long borne a sinister meaning; 2nd, an early diagnosis is often difficult, and 3rd, without an early diagnosis (and alas, too often with it!) the unfortunate sufferer has nothing left to do but say his prayers and wait patiently for the end. To be convinced that this last statement is painfully true, one has only to consult the statistical tables of those who possess authority to speak upon the subject. Treves estimates the percentage of recovery after operation in all forms of intestinal obstruction taken together at about 50 per cent. Taylor states in an excellent review of the subject that the present mortality following (but not caused by) the operation, for acute intestinal obstruction, is not far short of 60 per cent. In Curtis's tables of 247 cases where the cause of the obstruction was removed, the mortality was 62.7 per cent; while in 74 instances where this was not done the mortality was 86.4 per cent. Of 288 cases of ileus studied by Nannyn, recoveries by laparotomy on the first and second day amounted to 75 per cent; whereas on the third day only 35 to 40 per cent, could be saved. This last statement shows, therefore, the imperative need of early diagnosis in all cases of intestinal obstruction. "But how are we to make this early diagnosis?" I hear some one ask. There is only one answer to this query; viz., a thorough knowledge of the different varieties of intestinal obstruction, their signs and symptoms, and the ability to apply this knowledge at the bedside.

The late lamented, Prof. P. S. Conner was wont to express frequently before his class at the Medical College of Ohio this weighty aphorism: "Gentlemen, learn something of

*Read before the Kentucky State Medical Association, Paducah.

every thing, and *every thing* of something."

With this wise injunction before us, let us try to learn something, at least, from the pathology and symptoms of intestinal obstruction that will enable us to make an early diagnosis.

In doing this (I will ask pardon beforehand), it will be necessary to treat the subject in an elementary way that to most of you may appear commonplace.

The names intestinal obstruction, ileus, volvulus, iliac passion, intestinal occlusion, and intestinal strangulation have been long employed more or less confusedly, to denote a symptom complex characterized by abdominal pain, vomiting, arrest of the fecal current, and meteorismus. In the choice of terms Dieulafoy prefers that of intestinal occlusion as more applicable to all forms of intestinal obliteration, while most German and English writers adhere to ileus or intestinal obstruction. As the last two terms are perhaps the most generally used the writer will not depart from that usage. *Ileus*, then, may be defined as a term employed not to indicate a special pathological condition, but a group of symptoms among which four are more or less prominent; viz., (1) Abdominal pain, (2) vomiting of bile and fecal matter, (3) arrest of the fecal current, and (4) meteorismus. The presence of this symptom complex is always serious, as it indicates an obstruction to the fecal current which may quickly terminate the individual's life. *Ileus* has been classed as follows:

(1) Adynamic Ileus.

(2) Mechanical ileus, (a) from strangulation, (b) from obturation.

Either of these two latter varieties may be acute or chronic, an important division to be kept in mind.

Ileus is called adynamic when it results from failure of peristaltic action; mechanical, when it results from some closure of the intestinal lumen. Murphy would add a third variety; so-called dynamic ileus when there is excessive muscular power, as sometimes occurs in lead and tyrotoxic poisoning, etc.

The cause of adynamic ileus are many and will be stated as briefly as possible

(1) Central—Lesions of the brain and spinal cord.

(2) Reflex—Among the more common of the reflex causes may be mentioned, the strangulation of a piece of omentum in one of the hernial rings; renal or hepatic colic, the ligation of pedicles *en masse*; ovarian or testicular compression; blows upon the abdomen and operation upon hemorrhoids, etc.

(3) Inflammatory The most common cause is acute peritonitis—localized or diffused:

First of all local peritonitis such as sur-

rounds the appendix, gall bladder or Fallopian tube in its acute manifestations; in fact, localized peritonitis of any of the abdominal viscera. Diaphragmatic pleurisy and deep lobar pneumonia are not to be overlooked in the case of children. In the case of diffuse peritonitis, it is a common observation that it is often difficult or impossible to differentiate it from mechanical ileus.

MECHANICAL ILEUS.

In mechanical ileus the lumen of the bowel may be closed by pressure from without or by some obstacle within it; in the former case it is known as strangulation, and in the latter as obturation; but with this distinctive difference, that in strangulation not only is the lumen of the bowels compressed but likewise its mesentery and vessels to a dangerous extent.

The causes of strangulation ileus are manifold, and may arise from constrictions by bands or adhesions; Meckel's diverticulum, the appendix or the Fallopian tube may become wound around some hollow viscus and obstruct its lumen; a rent in the omentum, mesentery, broad ligament, suspensory ligament of the liver, or parietal peritoneum from defective development or traumatism may produce a like result, and the various forms of hernia both external and internal, intussusception and volvulus play a prominent role as causative factors.

Among the leading causes of obturation ileus may be mentioned foreign bodies such as have been swallowed accidentally or intentionally; biliary calculi, enteroliths, and fecal concretions. Carcinoma, most common in the colon and rectum is a frequent cause, while sarcoma and lymphosarcoma rarely produce obstruction. Tubercular, syphilitic, dysenteric and stercoral ulceration followed by stricture of the bowel are not infrequent causes. Compression of the lumen of the bowel by intra-abdominal growths, such as ovarian and uterine tumors; and chronic peritonitis, carcinomatous or tubercular, as well as chronic intussusception, help to swell this already formidable list. Last but not least is that rare form of obstruction known as the gastro-mesenteric ileus of Zade, due to occlusion of the duodenum by the superior mesenteric vessels.

Before entering upon the subject of symptoms and diagnosis it may make the interpretation of both clearer first to state three axiomatic principles that abundant observation and experimentation upon animals have fully demonstrated:

(1) In acute peritonitis the wall of the affected intestine is paralyzed, this portion becomes distended with gas and its mobility is limited.

(2) When a coil of intestine with its mes-

entery is strangulated there follows acute swelling of the affected portion. As the loop of intestine is mechanically fixed at the point of constriction it cannot move, and all peristaltic action is stopped by alterations in the innervation and circulation; there is a discharge of fluid from the strangulated part which within twelve hours may reach a considerable quantity in the peritoneal cavity. The bowel below the constricted portion is empty and collapsed, while that above is more or less distended according to the time of obstruction; in general it is true, that it gradually becomes filled with fluid and distended with gas.

(3) In obstruction of the intestine that portion below the obstacle is empty and collapsed, while that above it is very full; this distention decreases from the point of the obstruction toward the stomach.

As long as there is no peritonitis peristaltic action continues in the distended intestine, but is of varying intensity. If the obstruction is superimposed upon an existing stenosis due to a gradual narrowing of the intestinal lumen the muscular coat of the bowel above will have become hypertrophied and its peristaltic action exaggerated.

SYMPTOMS.

As a corollary to the above facts it may be stated, in general, that four cardinal symptoms of ileus are: (1) Abdominal pain, (2) vomiting, (3) arrest of the fecal current, and (4) meteorismus—symptoms that should at once direct the medical attendant to a careful scrutiny of his patient.

DIAGNOSIS.

It goes without saying that it behooves the physician or surgeon when called to a supposed case of ileus to make the diagnosis at the earliest possible moment, for every hour of delay in this respect only hastens the fatal end for the patient.

To the careful observer, in the majority of cases the diagnosis of ileus is apparent; the difficulty consists in the determination of the site and the cause of the ileus; but in most cases it is unnecessary to do more than determine whether the ileus is adynamic, or due to strangulation or obstruction.

In certain cases one or more of these causes may act in combination, in fact, it is not an uncommon thing to find this state of affairs existing, and it is in such instances that the most experienced diagnostician will be sorely baffled. In many cases a careful history will not only give us a clue, but make the diagnosis of the cause of the ileus. The next step should be a thorough examination of the patient. While attention is especially directed toward the intestines, the other organs

both within and without the abdomen should be carefully examined. The demonstrable changes to be expected in the intestine will be a modification of its form and its mobility. The examiner should next ask himself the question: Is peritonitis present? In most cases the answer to this question will not be difficult. If the abdomen is everywhere sensitive; if there is absolute constipation and the continuous vomiting of biliary or fecal matter; if the patient is restless and has drawn facies and hollow lack lustre eyes; if respiration is shallow and of the costal type, and there are moderate elevation or subnormal temperature with rapid compressible pulse; if there is dry red tongue, great thirst and scanty urinary secretion; if the abdomen is uniformly distended without visible or palpable intestinal coils, and if no peristaltic action can be heard the picture of diffuse peritonitis is typical. The absence of visible intestinal coils is significant; it indicates an extensive intestinal paralysis, such as accompanies acute diffuse peritonitis. Meteorism is as pronounced in the early stages of adynamic ileus, particularly the peritonitic type, as it is in the mechanical form. Borborygmus is always absent in adynamic ileus, while it is one of the most pronounced manifestations of the mechanical variety. The stethoscope will render valuable services in such cases. The temperature is of uncertain value in many cases of peritonitis, as it may be elevated, normal, or subnormal, although the rule is moderate elevation at the beginning.

While, therefore, in a doubtful case the presence of fever is suggestive of peritonitis its absence is no proof that peritonitis does not exist. The leucocyte count, the opsonic index, and the indican test have all been tried, and found wanting from a differential standpoint.

In strangulation ileus the acute onset, the sharp abdominal pain, the stercoraceous vomiting, the arrest of fecal current, the meteorisms, the marked depression and the absence of temperature, make a marked contrast to the above picture. The ear or stethoscope applied to the abdomen in the early stages of strangulation ileus may detect an increased peristaltic action, but not as marked as that observed in the obturation. In ileus due to obturation the picture is entirely different. With but few exceptions the onset is gradual; there is in the majority of cases a history of preceding abdominal disorder extending over a longer or shorter period of time; pain is not so acute and is more of a colicky nature; vomiting and distention come on more or less slowly; distinctly visible peristalsis and quite audible borborygmi are easily to be seen and heard; temperature is wanting, obstipation is

absolute. In obturation due to sudden occlusion of the bowels the onset and symptoms may be as sudden and intense as in strangulation ileus, and conversely, the latter may pursue a sub-acute or chronic course. It must not be forgotten that certain poisons, such as lead, etc., may produce symptoms closely simulating acute or chronic ileus.

Perhaps the above conditions may be made clearer by illustrating each variety with a case typically representative of its group.

ADANAMIC ILEUS.

Case I. Mr. McC., age 23, suffered about the middle of February, 1910, with an attack of acute perforative appendicitis attended by diffuse peritonitis. The only operative procedure indicated at this time was drainage, with the patient in the Fowler position. After a prolonged and stormy convalescence he made a good recovery, and remained free from any disturbance until February, 1911. At this time while engaged at his occupation in a rolling mill he began to suffer with colicky pains in the abdomen, but as this condition is not uncommon among this class of workers he paid no heed to it at first. After suffering for a few days without relief his medical attendant was consulted.

Examination disclosed at this time that he had a temperature of 100 degrees F. pulse 90; that there were nausea and cramp-like pain in the abdomen which was slightly tender to pressure at various points, and that the bowels were sluggish. There was no rigidity of the abdominal muscles to be detected at this time.

The condition gradually grew worse; pain was more severe and diffuse; the abdomen became markedly distended, and tender to pressure; retching and vomiting were now frequent and the bowels absolutely constipated, and no peristaltic action could be made out on examination; the temperature at some points in the 24 hours registered 102 degrees F. and the pulse 115 to 120 per minute. At the beginning of the trouble a tentative diagnosis of ileus due to post operative adhesions was made, but this was later changed to that of diffuse peritonitis.

Following the advice of Treeves, in such cases, we decided to open the abdomen, incise a presenting loop of bowel, and wash it out with the hopes of getting rid of a large amount of toxic material. This procedure was carried out as quickly as was expedient with thorough work, but it proved of no material value, as the patient gradually sank and died within twelve hours. The operation disclosed the absence of the supposed adhesions, and instead, a diffuse peritonitis among the coils of the small intestines.

STRANGULATION ILEUS.

Case II. Baby S., one year of age, robust hearty, breast fed child was taken suddenly ill on the morning of July 14, 1911, with severe colicky pains in the abdomen. Dr. G. W. Moore, the family physician, was speedily called and administered the usual remedies appropriate to colicky infants. The remedies did not bring about the expected relief, and it was soon apparent that something more serious than colic affected the child. He now appeared listless had vomited a time or two, and had passed with considerable straining and tenesmus several small bloody mucoid movements from the bowels. Pulse and temperature about normal. The writer saw the case with Dr. Moore at about 4 p. m. and in addition to the symptoms above detailed, there was no difficulty in detecting through the abdominal walls the presence of a doughy, sausage-shaped mass occupying the right lumbar and umbilical regions.

The presence of the mass, along with the age of the patient, the sudden onset, the bloody mucoid stools passed with great tenesmus, and the absence of fever made up a typical picture of acute strangulation ileus due to intussusception. Acting on this diagnosis the child was immediately transferred from its home to the King's Daughters' Hospital, where with the assistance of Drs. G. W. Moore and J. M. Salmon the abdomen was opened without delay. The incision revealed an acute intussusception of the ileo colic type, with perhaps 18 inches of the ileum invaginated into the colon. Reduction was accomplished without very great effort, a long appendix quickly excised, and a reef put in the mesentery with the hopes of preventing a recurrence. The entire operation consumed about 30 minutes, the child leaving the operating table in splendid shape. Briefly, recovery was complete, notwithstanding the development of a light attack of ileo-colitis which caused some apprehension for a few days.

OBTURATION ILEUS.

Case III. Mr. M., age 57; druggist had for several months complained of pain in abdomen and increasing difficulty of securing a bowel movement. He had been gradually losing weight and strength, but still continued in the active management of a large drug business. This he had been able to do up to three days before the writer saw him. At that time the patient's bowels had not moved for several days despite various strong purgatives which he had taken *ad nauseam*. He complained of cramp-like pains in the abdomen, and had vomited several times small quantities of brownish fluid, without fecal odor.

Examination revealed a markedly distended abdomen, through the thin walls of which inflated loops of bowel could be seen plainly. Exaggerated peristaltic action and loud borborygni were too evident to be overlooked by the most careless observer. Temperature normal; pulse of fair volume, and but slightly accelerated. Diagnosis: Mechanical ileus; probably malignant. Operation revealed a stricture of the bowel at the junction of the descending colon with the sigmoid. Owing to the fair condition of the patient and the free mobility of the growth it was deemed expedient to excise it. Accordingly, resection of the affected segment followed by end-to-end anastomosis with a large size Murphy button was performed as quickly as possible. Despite our judgment the shock of the operation proved too strong, and the patient succumbed to it five or six hours later. The specimen removed proved to be a carcinoma of the circular, stenosing variety, with a small excentrically placed opening, barely large enough to admit a probe three millimeters in diameter.

From the above detailed description of ileus, amplified by case reports it will be seen that the direct diagnosis is not often difficult, but the differential diagnosis may offer insurmountable difficulties. As has been already pointed out it is rarely necessary to do more than determine whether the ileus is adynamic, or due to strangulation or obstruction. To burden you with the differential diagnosis of the various anatomico-pathological varieties of intestinal obstruction would take me far beyond the scope of this paper.

Suffice it to say that upon the early diagnosis of ileus, as in acute appendicitis, hangs the life of the patient, and if you are not able to make this early diagnosis by all means *do not* delay calling to your aid a competent consultant. Conscientiously, and for obvious reasons, withhold all purgatives and opiates until a diagnosis has been made, then treat the case accordingly.

EARLY DIAGNOSIS OF ANO-RECTAL DISEASE.*

By J. G. CARPENTER, Stanford.

If there is any specialty on the face of the earth in which the general practitioner can be a specialist it is in ano-rectal diseases. He can treat all of them if he has prepared himself to do this work.

Early diagnosis in ano-rectal diseases is everything. Too often in the past we have submitted to subjective examinations; we have taken what the patient has said, but that is wrong. They need objective examinations.

If a patient will not submit to a proper objective examination, that patient has no right to be treated. As a practitioner you must be the king or prince of the situation.

Even in children we find cases of ano-rectal diseases. I have seen young children with summer diarrhoea who had fissure, hemorrhoids, aphthous ulcerations and proctitis, and by divulsing the rectum, and using antiseptic treatment these little patients have recovered, and the summer diarrhea has subsided on account of the good rectal treatment. We must use digital examination and find if there is an erythema of the anus, an excoriation, whether there is a fissure, or whether there are hemorrhoids or whether there is rectal hemorrhage.

Again, with digital examination we may find disease of the adjacent structures. There may be vesical calculus, uterine displacement, prolapse of the ovaries, or uterine fibroids. Again, we may find polyps or fibroid of the rectum by digital examination, a cancer or a sarcoma, or a stricture, as the case may be. With ocular inspection we can determine whether there is an excoriation of the fissure or of the ulcer or whether there is a stricture of the rectum, or whether the rectum is occupied by a growth of some kind. We can easily determine whether there is an ulceration or a proctitis. Again, by illumination we can see whether there is an abrasion of the sigmoid, a stricture, a tumor, or a hyperplasia. It is surprising how much can be seen. A good deal will depend upon whether the physicians uses the position of Carpenter, Hanes or Kelly. By the way, allow me to say in this connection, that I am the father of the sigmoidoscopy. I am the first man in the world who ever illuminated the sigmoid. While Dr. Kelly claimed it, he did not press his claim and gave me credit before the surgical section of the American Medical Association at Atlanta. When the speaker did his first sigmoidoscopy and a number of them subsequently, Dr. Kelly had not become a physician.

Again, from rectal diseases we will have rectal reflexes, palpitation of the heart. We will have chest pain, lumbar pain. We will have neuralgia, and by curing the rectal trouble you will cure the other troubles. That is very important. Some of the most pronounced cases of neurasthenia, we see are due to rectal diseases, and by curing the disease of the rectum you will cure the patient. So do not forget that a papilloma will cause the most intense rectal hyperesthesia and pruritis ani. I have been surprised at the results of some rectal surgeons who in their operative work have left large pieces of piles, not having given their cases proper attention. The patients have not been operated upon proper-

*Read before the Kentucky State Medical Association, Paducah.

ly, but they have left great tags around the rectum at the anal margins to itch and cause pain and annoyance, and some of these patients do not get relief until they fall into the hands of a good country doctor. (Applause). No man can be a good rectologist unless he is a genito-urinary specialist, unless he is a gynecologist and abdominal surgeon. It is surprising to me of late how eager the rectal specialists are taking to abdominal surgery. Do not forget that a good practitioner divulses the sphincters and cures three-quarters of the cases by it, such as cases of fissures and ulcers and hemorrhoids.

As to the diagnosis, you can use the sunlight on a bright day. When you cannot do this, you can use an electric light, or if you are in the backwoods you can use a tallow candle and a head mirror to illuminate the sigmoid, as I have done, and you can all do this if you want to. Remember, a good diagnosis in ano-rectal diseases is everything. You practitioners should make these diagnoses as early as possible, and institute early treatment, collect an early fee, and have these patients stay at home where they can receive the best attention, and where you can get the most reputation. (Applause).

THE IMPORTANCE OF EARLY DIAGNOSIS OF ECTOPIC PREGNANCY.*

By HUGH E. PRATHER, Hickman.

"When the fertilized ovum is arrested at any point between the Graafian follicle and the uterine cavity, and there undergoes development, we designate the condition as an extra-uterine or an ectopic pregnancy. • • • Unless artificially relieved, an ectopic pregnancy always terminates fatally to the child and is frequently fatal to the mother." (Kelly).

Abdominal section, in my opinion, is the only reliable method for the relief of this condition. Hirst states that, without surgical treatment, about two-thirds of these cases die. So great a man as Howard A. Kelly has said: "The proposal to defer the active treatment of an extrauterine pregnancy, in its early stages, in the interest of the child, is simply sentimentality." In order that the greatest number of lives may be saved, it is absolutely necessary to make the earliest possible diagnosis. This is not easy to do before primary rupture, which often occurs from the 4th to the 8th week. We should be particularly on the outlook for ectopic gestation in those women of child-bearing age in whom an interval of several years has elapsed since the birth of the last child, or who give a his-

tory of a previous extrauterine pregnancy, or some tubal affection.

Many of these patients will give a history of having missed one or more menstrual periods; or, after having missed a period, two or three weeks later will develop a flow of a tarry, sticky character, which continues for ten days or more. Upon careful microscopic examination of this uterine hemorrhage, decidual cells will often be revealed.

The patient usually has nausea with changes in the breasts and in the color of the genital mucous membranes, and after the third month, the presence of colostrum.

Physical examination may reveal an enlargement anterior, posterior, or lateral to the uterus and causing its displacement, which may have a doughy or elastic feel, and should be handled very carefully as a precaution against rupturing it.

The patient usually complains of sharp colicky pains, due to uterine contractions and, if accompanied by faintness, indicates a partial rupture. Often the uterus is slightly enlarged and the cervix softened.

When rupture occurs, the patient may suddenly collapse and fall to the floor, or present symptoms which simulate salpingitis, appendicitis, or uterine abortion. In salpingitis and appendicitis, however, we would expect to find an absence of any symptoms of pregnancy. The absence of any rigidity of the abdominal muscles will help to eliminate appendicitis. Furthermore, these conditions are usually accompanied by a rise in temperature, while the reverse is true in ruptured tubal pregnancy, although we may later have a rise in temperature due to infection. In uterine abortion we would expect to find a dilated cervix and the absence of any abdominal mass near the uterus. In uterine abortion the pain is more frequently in the lumbar region, while in ectopic it is distributed over the lower abdomen. Also, a microscopic examination of the discharge would show decidual cells with an absence of chorionic villi which would be present in uterine abortion. Boldt calls attention to a sharp lancing pain in the rectum in these cases. Blood examinations are of little value.

Surgical treatment should be instituted as soon as the diagnosis is tentatively established, except in those cases in extremis.

When unable to differentiate between *tinea circinata* and *eczema*, resort to the microscope; the presence or absence of the characteristic fungus of *tinea* will settle the question.

Much-Holtzmann Reaction.—The authors concur in the prevalent conclusion that the Much-Holtzmann reaction has no diagnostic significance.

*Read before Kentucky State Medical Association, Paducah, October, 1911.

DIAGNOSIS OF HEAD INJURIES.*

By A. D. WILLMOTH, Louisville.

In the absence of Dr. Letcher, who was to have contributed a paper on this subject, I have been asked by our President to make some remarks on this subject, which I have consented to do.

You have heard from the previous speakers, beginning with my friend Dr. Wathen, how important it is to diagnose cancer in various portions of the body; you have likewise heard from Dr. Carpenter relative to the importance of diagnosing diseases of the rectum, and it is with no little hesitation that I shall try to tell you how especially important it is to diagnose injuries of highly organized tissue such as the brain. With all of the emphasis that has been put on the other papers in this symposium, I will say to you, in the brain, of all structures, do we have to make an early diagnosis if we expect to get the best results. This may mean a surgical result. Many times it means doing nothing. The results, as I take it, are those, first, that bring the best chances to the patient for recovery; second, those that bring results to the friends of these patients. What I mean by that is this: if the cases are clearly inoperable when an early diagnosis is made we can tell the friends about it, and an operation is avoided, and thereby we do not cast opprobrium on the whole field of surgery and get condemnation heaped upon our heads for operating on inoperable cases. If we would make early diagnosis we have to do away with the old classification that has been laid down from time immemorial of concussion and compression of the brain. Even to-day, if we look over many of the medical journals and most of our text books, we will find that authors still adhere to the old classification; that they speak of concussion and compression of the brain, the first term really meaning nothing. There is just one condition in brain injuries that brings about the entire trouble, and that is the increased intracranial pressure. We have been clearly taught by Frazier and by Cushing in particular that all conditions in the brain are brought about by increased intracranial pressure. If this increased intracranial pressure is due to an injury, we merely have an extravasation of blood as in any other part of the body or tissues. Such hemorrhage being either or both epidural or subdural, but the symptoms are quite as frequent by encroachment of the boggy brain upon its vascular and plasma channels. If the increase in blood pressure is sufficient to overcome the effects of this increased tension the patient will recover, while

on the other hand if the heart is unable to cope with the obstruction to the cerebral circulation an anaemia of the vital centers takes place which if unrelieved proves fatal. Of course all are aware that injury to important centers can take place at the instant the trauma is sustained.

The facts being true all brain cases should be divided into four classes, first, those in which the injury is so slight, recovery will take place in every case without interference. Second, those in which the injury is so great death will result it matters not what is done. Third, those with local lesions and focal symptoms where interference is clearly indicated. Fourth, those of borderline type where symptoms for and against operations are equally divided.

There are some points in brain injuries that we fail to look for close enough. What are we going to do, or what are we not going to do, for the cases that present themselves to us for final decision? First and foremost, I think, we pay too little attention to the history of the cases. In most instances we are prone to look on the case with grave doubt when we see the patient at the time we are called in. If we will take the trouble to get a clean-cut history, if such is possible, although I recognize in our hospital work, where patients are brought in by the police patrol or in an ambulance, with no history practically, this is many times difficult to obtain, but in the average case there is some one present or there may be some one near enough at the time of the injury from whom you can get a clear history. If we take the trouble to get such a history, or if the case has been treated by some physician before we are called in to render a final decision, we will undoubtedly get points of information that are of especial importance. It is important from the history to know whether or not the patient has been wholly unconscious from the moment of the receipt of the injury. If the patient has been wholly unconscious from the time he sustained the injury, I think it is Frazier who says that in most instances the last named cases are of such a character that we had better let them alone; that the brain in most of these instances has been severely lacerated, and that any operation we do will do the patient no good. The patient dies sooner or later, and the impression made upon the family by the operation is not a favorable one, for they are unable to appreciate the difficulties under which we labored. When a man receives an injury and gets up off the ground after he has received a blow, and later becomes unconscious, you have a clear history that the case is probably one of hemorrhage, and it is a question of localization of it, and of dealing with it surgically.

*Read before the Kentucky State Medical Association, Paducah, 1911.

Another point we fail to look for close enough in these cases is to make use of lumbar puncture. In many instances, in cases that are brought into the hospital, if you are able to get a correct history that shows that the patient was unconscious from the beginning, if you make a lumbar puncture, you will be rewarded in many such instances, by removing evidences of the hemorrhage which means that the patient has sustained a severe laceration opening up the channels, allowing the blood to get down there, and you know very well what the result is going to be in such a case, and in many instances it will prevent operating on cases that are clearly inoperable. So also will changes in the circulation show evidences of encroachment on important centers.

Let me mention another point in connection with the early diagnosis. In a case of hemorrhage in the brain there are variations in temperature in various parts of the body, as, for instance, in the axillae. Where these patients are brought to the hospital unconscious, with or without a dilated pupil in one or both eyes, it will lead you to one side or the other of the brain. If you take the trouble to take the temperature in the two axillae with the same thermometer, with the same care, you will find in the axilla on the opposite side from the injury a temperature higher than it is on the side where you expect to find the blood clot. That means to you that the clot is on the other side. If you have a temperature which is much higher in the left axilla, then the trouble is likely in the right side of the brain. You will have paralysis of the extremities in the opposite side of the brain, showing clearly that he hemorrhage is on that side.

Another thing that is of special importance is to make as early a diagnosis as possible in order to do something radical to cope with the pathological condition before there has been a great deal of damage done to the brain structure. It matters not whether it be a hemorrhage or pressure. If you have a hemorrhage that is producing pressure, that is extra-dural, the sooner you get in there the less blood will be lost, and the less pressure there will be to the important structures, and the less likely is the patient to have other conditions following that. If the hemorrhage is intra-dural, it is more important to make an early diagnosis and to do what you can for the patient. In this class of cases, where there is rupture of the brain, more or less damage being done to the brain structure, where there is hemorrhage at the base of the brain, we should strive to do for that patient what Frazier has done, namely, a decompression operation. Of course, this would be considered a radical operative measure, but he

has proven that we have pressure to deal with, and it is not so much a clot or hemorrhage itself at any particular point, but it is the increased intracranial pressure that causes the patient serious trouble and is finally the cause of death in these cases. A decompression operation made through the temporal region will in many cases give relief. Those of you who have followed closely his writings, will remember the brilliant results he has had along this particular line.

Another reason why early diagnosis is indicated is to lessen the pathological conditions that are present or limit them to a minimum, so that there may be no complications following. In many instances you will avoid such a serious complication as Jacksonian epilepsy.

Some few months ago in the JOURNAL I reported a number of cases on which I operated, with some good results along this line. There were not only injuries to the skull itself, but in other instances there were injuries of the brain structure, the cortical substance, or of the membranes covering the brain. A careful diagnosis in such cases as these would lead to interference and proper treatment of conditions which later on, as the result of adhesions, lead to the development of Jacksonian epilepsy, requiring a great deal of operative interference to relieve them, with the possibility of not being able to relieve them at all because of the fact that the epileptic habit has been established. This condition is one with which you are all familiar, and one, as you all know, which may cause a patient to have attacks even after the pathological condition has been relieved. Therefore I say, in the injuries of the brain, of all structures, it is certainly important that an early diagnosis should be made, that we may be able to know just what we are going to do. It is just as important to say no as it is to say yes, and to give the family the reasons why. If you think the patient is going to die, it is important that a very careful, painstaking diagnosis be made, and that a grave prognosis be given to the family. Unless you make a careful diagnosis and inform the family of it you had better stay away from the patient. Such a patient is likely to die in a few hours, and it is much better that he should die without surgery than with it, because if you should operate on such a case and the patient should die you would get blamed, no matter what the pathological condition was that indicated the operative interference..

Influence of Calcerous Drinking-Water.—Lewis claims that here is no evidence that hard water has any bad effect; on the contrary, all the evidence is the other way.

THE IMPORTANCE OF THE EARLY DIAGNOSIS OF PLACENTA PREVIA.*

By J. T. REDDICK, Paducah.

A recent contribution to medical literature informs us that in twenty-five thousand recent consecutive deliveries in Sloan Hospital New York, there were 223 cases of placenta previa, or 1 in 112. This, of course, is a somewhat greater frequency than occurs in private practice for the reason that many cases which if normal would have been treated at home, are sent to the hospital on account of the complication. (1)

Statistics show that the infant mortality in placenta previa is between fifty and sixty percent and the maternal mortality is ten to fifteen per cent or more. This being true it is a formidable condition to treat and its early recognition becomes a matter of great importance to the obstetrician.

In no other condition of pregnancy is the danger to life so imminent, in no other is a knowledge of the proper methods for averting this danger so essential, and in no other is a judicious discrimination as to the relative value of each of the several procedures so necessary as in placenta previa.

The prominent indication of placenta previa is hemorrhage, and this symptom alone is all that is necessary to call our attention to the probability of placenta previa, and, this symptom alone is all that requires attention in the way of treatment.

The hemorrhage of placenta previa is characterized as unavoidable in contradistinction to other obstetrical hemorrhages, more especially that designated "accidental."

The hemorrhage occurs during pregnancy or labor, and may occur as early as the fourth or fifth month. It is very probable that many abortions and miscarriages are instances of placenta previa in which the true condition is unrecognized.

Every case of hemorrhage occurring during pregnancy should receive the prompt attention of patient and obstetrician and much depends upon the proper care and treatment of the patient as to the final outcome of the case.

During pregnancy the hemorrhage is not apt to be dangerous but at the end of gestation or the beginning of labor, it may in a few moments place life in the greatest danger.

However, a considerable amount of bright vaginal hemorrhage occurring during pregnancy is always a symptom requiring prompt attention, and if occurring during the latter weeks of pregnancy should be considered as indicating a critical condition and should be

seen by a competent obstetrician and prompt efforts be made to avert a sudden dangerous hemorrhage.

The treatment of placenta previa as previously stated, is essentially that of hemorrhage, hence the importance of an early diagnosis as no one plan is applicable to all cases.

The period of pregnancy or stage of labor at which the hemorrhage is first observed, and the situation of the placenta must, of necessity, govern the treatment.

If the hemorrhage occurs during the early months of pregnancy and a positive diagnosis can be made, and an abortion does not occur, it may be advisable to empty the uterus under modern well-known rules of procedure.

After the viability of the child, it claims consideration, but as fetal mortality is high under the most favorable conditions and with the most approved treatment the child's claims are not to be weighed against the risk of the mother's life.

Again, the accuracy of an early diagnosis is important as bearing upon the treatment of the case, in, that there must be considered the extent of the first hemorrhage, and its effect upon the mother and fetus. If the child dies there can be no reason for further delay in emptying the uterus. If the mother should, by reason of the hemorrhage, be brought to an extremely critical condition further delay is not justified except for resuscitation.

DISCUSSION.

W. W. Anderson, Newport: One of the unfortunate things that sometimes happens to the patient who is in need of an early diagnosis is that he is put upon expectant treatment. For instance, the patient presents himself with an obscure history of gastric pain. Without taking the trouble to go into the case carefully the practitioner puts this patient on expectant treatment. Again the case may be one of irregular uterine hemorrhage. The doctor suspects that surgical intervention may be necessary. Perhaps he is not a surgeon and could not give proper surgical treatment. Therefore he puts the patient on expectant treatment.

The first of these doctors is criminally careless and the second criminally selfish. In either instance such expectant treatment is expecting the patient to recover spontaneously, or develop symptoms that proclaim the diagnosis without the trouble of study.

In such hands the "day of grace is sinned away," and gastric hyperacidity which is curable goes on to ulcer which is less amenable to treatment and ulcer goes on to cancer and death.

*Read before the Kentucky State Medical Association, Paducah, 1911.

The uterine hemorrhage of incipient malignancy is allowed to go on to the foul discharge of necrotic cancer too widespread to remove.

The ruptured appendix, the gangrenous gut of hernia, the delayed antitoxin in diphtheria and tetanus, and the fresh air only after there is scarcely lung enough left to use it, all these belong to an expectant treatment which seems to expect the patient to die and he usually fulfills the expectation.

Whenever the case presents symptoms in the least degree suggestive of malignancy either internal or external the necessity for diagnosis is urgent. Sometimes the diagnosis can be made promptly by the medical man. Usually the differentiation in his unaided hands is slow. We have seen long and patient effort in this line result in a brilliant diagnosis of cancer of the sigmoid, and witnessed the postmortem confirmation. But all this was of no value to the patient.

For the general practitioner there are but two points of legitimate contact with malignancy; first to make a diagnosis and last to relieve suffering in hopeless cases. The diagnosis by medical examination is difficult. Surgery is so safe, so swift and so sure that we ought to make more use than we do of the surgeon in establishing the early diagnosis of malignant disease.

There is no medical treatment of cancer. Hence when its presence is known the case belongs absolutely to the surgeon and it is clearly our duty to get out of his way.

J. G. Carpenter, Stanford: I wish to say a word with reference to the early diagnosis of ectopic pregnancy. This is a most vital subject. It is unfortunate for a woman to have an ectopic pregnancy, yet the old saying is that "the early bird catches the worm," and early diagnosis is everything to the patient and to the physician. We should make a diagnosis before rupture of the tube. We have the subjective symptoms of pregnancy. We have the objective symptoms of softening of the uterus, discoloration of the birth canal, enlargement of the uterus, a change in the position of the uterus, a shortened cervix, an enlarged fundus, and then there has been usually a period of sterility, with a history of ovarian and tubal disease, and enlargement of the uterus. A patient may feel in unusually good health, when suddenly in doing something she falls over and faints, or she has an attack of violent pain in the lower part of the abdomen and exclaims "My God, I am dying." The voice is husky and whispered. The skin becomes cold and clammy; the pulse throbs; the eyes glassy; the features are pinched, and then there is that anxious expression of "God save me, if you can." By digital examination we find the conditions of the uterus that I have mentioned. Where there is rupture, you will find the broad ligaments and fornices filled, tense and doughy and elastic, indicating hematocele. Again, by rectal examination you will find supra and lateral intra-peritoneal pres-

sure from hemorrhage, including the rectum, where rupture has taken place. It seems to me, with this clinical picture most practitioners should be able to diagnose ruptured ectopic pregnancy.

Again, ruptured ectopic pregnancy takes place between the folds of the ligament in the third month, but the landmarks to survey are the sterility, the tubal disease, the enlarged and softened uterus, and so on.

Again, another point is that the tube may not have ruptured. The patient may go on until the sixth or eighth or even ninth month with ectopic pregnancy, and the question arises, is there an ectopic pregnancy, a fibroid, a multilocular ovarian cyst, and so on? After a diagnosis of ectopic pregnancy has been made we do not rush in rapidly where angels fear to tread, but we wait and bide our time, keep the patient in the best condition possible, and when the attachments of the after-birth are maturing and ready to undergo degeneration, we operate and save the lives of both the mother and child.

J. T. Reddick, Paducah: Dr. Carpenter has given a graphic description of one kind of case of rupture of the tube in ectopic pregnancy, but sometimes it is difficult to make a diagnosis. If you have a rupture in the early stage of pregnancy, that rupture is small, and the hemorrhage is small, you may not be able to make a diagnosis for several hours, as in one case that occurred in my own practice. In this case it was impossible to say whether or not it was a case of ectopic pregnancy with rupture, whether it was a case of appendicitis, or one of acute intestinal obstruction. The patient did not show these alarming symptoms immediately because the hemorrhage was light.

Dr. Carpenter says that we may be able to make the diagnosis before rupture, but frequently the physician is not called to see the patient until rupture has already taken place. I know it is very difficult frequently to make a diagnosis, and perhaps if you can get the patient to a hospital or get her on the operating table soon enough you will not make a diagnosis at all until you have opened the abdomen and have seen what the pathological condition is. In the case I refer to the patient was out in the lawn and was stricken with quite severe pain in the right side, and I gave it as my opinion at once it was a case of fulminating appendicitis, intestinal obstruction, or a ruptured tubal pregnancy. By the time we got her to the hospital, which was several hours afterwards, she had reached that stage with an alarming hemorrhage when it was possible to make an almost positive diagnosis of rupture because of the hemorrhage and the profound shock. She was so profoundly shocked from the hemorrhage she did not even know when she was taken to the hospital. Fortunately she recovered. We do not meet these cases very frequent-

ly which Dr. Carpenter has so graphically described.

Edward Spiedel, Louisville: When hemorrhage occurs suddenly in the latter half of pregnancy we must differentiate between an unavoidable hemorrhage, the hemorrhage from a normally implanted placenta. The differentiation is made through the definition of terms. An accidental hemorrhage due to separation of a normally implanted placenta is such as to cause sufficient disturbance to loosen the placenta and give rise to a hemorrhage behind the placenta; whereas nothing of the kind occurs in placenta previa. While we may not be able to make a diagnosis of placenta previa in all cases, we should know when our pregnant patients are predisposed to placenta previa and in the light of these events women are apparently more disposed than they were formerly. The statistics given by Dr. Reddick in connection with his case are much greater than the statistics found in the average textbook on obstetrics. Placenta previa is undoubtedly becoming much more frequent than formerly. In the last six months I have had six cases of placenta previa, four of which were of the central variety. I believe that the greater frequency of this condition is due to two conditions, namely, the greater frequency of gonorrheal endometritis and to the use of automobiles. The reason why gonorrheal endometritis predisposes a woman to placenta previa is on account of the pathological changes which occur in the endometrium, and in consequence of the gonorrheal infection the chilia on the mucous membrane disappear, and the ordinary cells are displaced by squamous epithelium, giving a feeble hold to the ovum as it reaches the loose membrane of the uterus, and in consequence the ovum slips farther down in the cavity of the uterus. And automobile riding causes a predisposition to placenta previa because it also dislodges the ovum, the constant jarring of the automobile giving rise to early abortion. If you take the previous history of cases of placenta previa you will find they will have two kinds of histories. They will give a history of previous abortion, or threatened abortion, that was arrested by medical means or by rest. That, of course, means that the ovum was dislodged; it secured a foothold lower down in the cervix and developed there again, the placenta spreading over the lower segment of the uterus and encroaching upon the internal os. In multipara especially the uterus is relaxed when placenta previa is present. That has been the history of the cases I have seen and have reported.

As to ectopic pregnancy, rupture usually takes place during the eighth week, or there is an abortion, and early diagnosis means a diagnosis before this time. In a woman of the childbearing age, one who is subjected to the possibility of impregnation, with the absence of the menstrual periods, we should be led to conclude that she is

pregnant. If in addition she complains of pain in one or the other ovarian region, particularly in a woman who has not had ovarian pains, it should lead us to make an examination in the early months, even in the first month of impregnation, but, of course, you would find few symptoms on vaginal examination. You may find an enlarged and soft uterus, but in a case of intrauterine pregnancy you will find on one side of the uterus an enlarged fluctuating mass which the previous history would indicate had not been there previously. When there is a flow of blood from the vagina the differentiation must be made between the return of blood from ordinary delayed menstruation, between the blood flowing from a threatened abortion, and between the characteristic bloody discharge that is incident to an extrauterine pregnancy. In ordinary menstruation, naturally the flow should be very much like that mentioned in the preceding history of menstruation, and vaginal examination should show no enlargement or softening of the uterus, nor any other signs of pregnancy. In a threatened abortion you will have an enlarged and softened uterus; you will have a flow of blood that largely consists of blood clots. In extrauterine pregnancy you will have a flow that is lighter in character than the ordinary menstrual flow, watery and bloody, but largely free from blood clots. It may contain decidua structures because the uterus under these circumstances contains decidua. Then by vaginal examination under these circumstances, you will find an enlarged and softened uterus, and on one side or other a tumor that shows the location of the ectopic pregnancy.

In regard to the treatment of placenta previa it consists of immediate evacuation of the uterus. I have been called to patients who were almost moribund and pulseless, and the only proper thing to do in these cases is to resort to vaginal tamponade sufficiently to control the hemorrhage until preparations for operation can be made, or the patient can be transferred to a hospital. Then commencing with manual dilatation and resorting to version.

In regard to the method of version that I described this morning in a case of placenta previa centralis, you would be astonished how nicely the placental tissue can be severed with the fingers and how easily you can work through the membranes that are left and reach the child through the membranes just as readily as if you had a lateral implantation of the placenta and no placental tissue to obstruct.

T. A. Frazer, Marion: I want to say just a few words in reference to the remarks that have been made by Dr. Wathen. He has said some very timely things in regard to the early diagnosis of malignant conditions, and one thing I regard as the keynote of his discussion of the subject was that the laity are not educated to understand the meaning of the symptoms. I want to

say further, that our doctors are too reticent; they are not taking the interest they should take in educating the laity, and especially in educating our women as to the meaning of these various discharges they may have from the uterus preceding fatal malignancy. We need to educate them to the importance of a little lump that may be felt in the mammary gland.

My experience with malignant diseases in country practice has been that the average doctor either does not suspect malignancy or he is afraid to tell his patient that she has malignant disease for fear she will go to some surgeon and that the surgeon will get the credit for making the diagnosis. I want to express my abiding faith in the surgeons of the country. I am glad that the day has come when we can entrust our patients to surgeons with that abiding faith, with that confidence that they are going to make these exploratory operations, if need be, to make a diagnosis; that they are going to make them safely and try to save the lives of the patients. While I believe in every man studying for himself—and the general practitioner should be the greatest specialists there is—yet I do not believe in any man in this day and age of the world undertaking to be a specialist when he is not qualified for it. However, I believe it is a day of specialism in surgery, and it stands to reason that the man who is operating very frequently can do better and more skillful work than the man who only does an operation occasionally. A butcher does his work over and over until he becomes expert. Our surgeons are careful, they do their work safely, and with modern asepsis which is carefully applied in the well equipped hospital, when I send a patient to a surgeon for operation I feel perfectly easy. I feel perfectly satisfied that the patient is in safe hands. We have many good surgeons, and there are but few of us who are not within easy reach of a good surgeon.

In regard to ectopic pregnancy, I want to relate a case in which I was called in consultation. This case occurred some five years ago. Dr. Daugherty reported this case to the association at the Owensboro meeting, but unfortunately it was just before the association adjourned, and there were not more than a dozen men to hear the paper. The case occurred in a woman, thirty-five years of age, who had had one child when she was seventeen years of age. She did not conceive any more up till this time. Dr. Daugherty was the family physician. They called him hurriedly as the woman had fainted. He reached the home and made a diagnosis of rupture of the tube, and called for me immediately. I got there and agreed with him in the diagnosis. We advised immediate operation, but the family objected, and said she might die, and they would not have her operated upon. We told them, of course, she would die without an operation. The case went along. The woman continued to live in spite of everything, and for days and days she was con-

fined to her bed. She was between the third and fourth months of pregnancy. According to my recollection, it was about nine weeks from the time of the first hemorrhage that she expelled the fetus from the rectum. We got the specimen and kept it. Dr. Daugherty had the specimen with him at the Owensboro meeting, and exhibited it. This woman got well. She is apparently in perfect health. I have examined her since, and I find that her vagina and rectum are so bound down by adhesions that it is impossible to make very much of an examination, yet she is apparently in good health. That is one of the extreme cases showing what nature will sometimes do; yet I would not have anyone infer that that is the best plan to manage these cases. I think these cases should be operated upon immediately.

William H. Wathen, Louisville: Intestinal obstruction is a subject in which we should all be much interested. I do not know of any condition that should be diagnosed earlier than intestinal obstruction. We must look upon it in the light of an abdominal catastrophe, and if the diagnosis is made promptly and operative interference resorted to, it will usually be successful. If operation is long delayed then no operation will be of benefit. All of these patients will then die. Of course, I have reference now to total acute obstruction.

There is one phase of this subject that I am going to speak of particularly; that is intestinal obstruction from appendicitis. This could be almost entirely avoided if the physician would interpret correctly the symptoms of acute appendicitis. This is easily done if the case is carefully observed. What are the symptoms? First and always pain, generally in the epigastric region, becoming sometimes diffuse, but localizing itself finally in the right iliac region; then rigidity of the abdominal muscles, next nausea and vomiting; later elevation of temperature and acceleration of pulse. When a child or an adult, and more especially a child, has an acute abdominal pain, very often it is an appendicitis; but the symptoms in an acute appendicitis in the child are not so marked except the pain, as in the adult. You may have an acute appendicitis with severe pain in a child with practically no abdominal rigidity; but finally the symptoms will otherwise develop practically as they do in appendicitis in an adult. I think if we would all watch carefully for these symptoms and interpret them correctly, if we would then educate ourselves never to give anything by the stomach, not even a drink of water, always avoiding purgatives, keep the patient quiet, apply an icebag over right inguinal region, we will seldom have a case of perforative or gangrenous appendicitis. This has been my experience in surgery of the appendix where there was a gangrenous or a perforated appendix; namely, on the first indication of pain

a purgative was given, and perforation later occurred.

I was much impressed recently in reading a paper which was sent to me by Mr. Moynihan, of Leeds, England, in which he reviewed his work in appendicitis for seven years, and in every case of gangrenous or perforative appendicitis a purgative had always been given. It is quite natural that a loving mother or a nurse should give a little child, especially, and even an adult suffering severely with acute abdominal pain, a purgative. Hence, this final cathartic has been the cause of innumerable deaths, and will continue to be unless we teach the profession, and teach the mothers and the nurses, never to give a purgative in any condition of severe pain in the abdomen until we have time to determine what the disease is. In acute intestinal obstruction from other causes, of course, no sensible person would think of giving a purgative or anything by the stomach. In these cases we should operate quickly, and when that is done we will save all our patients.

These cases of perforative appendicitis are nearly all of them therapeutic perforations and may never have resulted if the patient's stomach had been kept empty and no cathartics given. Why should you give anything by the stomach in appendicitis? It has been proven conclusively that even water taken into the stomach will cause active peristaltic action in the appendix, and cecum—a thing we do not want. Purgatives will increase the peristaltic movements of the intestines, and likewise the number and virulence of the bacteria in the ileo-cecal region, and the greatest number of virulent bacteria in the intestinal tract are found in the lower ileum and in the cecum on each side of the appendix. We must stop active peristalsis by keeping the stomach free of food, liquids or purgatives, and by thorough stomach lavage and aspirating all liquid from the stomach by the pump.

If in acute appendicitis, beginning with severe abdominal pain, we can put an end to the phloeoathartic propensities of doctors, mothers and nurses, there will be fewer gangrenous and perforated appendices resulting in the death of these patients. Unfortunately too many of our cases of acute appendicitis give the following history "Pain, purgation, perforation"—often death so easily prevented by correct treatment and timely surgical operation.

J. G. Carpenter, Stanford: I want to say a word or two more in regard to ectopic pregnancy. When a patient with ectopic pregnancy has a rupture, has symptoms of collapse and shock and fainting, and so on, she may recover; there may be contraction and retraction of the walls of the blood vessels, rupture plugged with a clot or much hemorrhage; or there will be a localized peritonitis in connection with rupture of the tube; the tube will have emptied itself, the placenta and fetus escaping into the peritoneal cavity. This

tube will heal over, and the patient will recover from the general condition of collapse and shock, get up and go about her work, and after a month or two months I have seen them going around with their abdomens full of blood, with fluctuation like ascites. On abdominal section, you will find that the peritoneum presents a dark discoloration, and I have always seen that dark discoloration of the peritoneum in ectopic pregnancy with much hemorrhage intra-peritoneal. To my mind it is a diagnostic measure. So these patients who have rupture do not all die. They may go around for weeks or months or more with the abdomen full of blood; or with high pulse and elevation of temperature. If you resort to abdominal section, do clean surgery, they will recover and go on their way rejoicing.

A. D. Willmoth, Louisville: I have nothing further to say on head injuries, but I wish to take the liberty of saying a few words in regard to intestinal obstruction and the indications for early diagnosis and give three don'ts for you to remember.

In those cases of abdominal pain, where you are in doubt as to the condition that is present, wash their bowels out, wash their stomachs out, keep water away from them, and remember three don'ts. Don't give any opium. Don't give anything in the stomach, and don't delay.

H. E. Prather, (closing the discussion): There were a good many points in connection with the diagnosis that I did not take up in my paper. In the interstitial variety of ectopic gestation, which is, where the impregnation is within the uterine wall. When rupture takes place we have the largest hemorrhages as a rule.

I did not try to differentiate between tubal abortion and tubal rupture, which occur at about the same time, although the importance of them is equal when it comes to treatment.

A very important point, and especially in order to make an early diagnosis, is to try to train our patients and those over whom we have any influence and tell them this, that whenever they have reason to believe themselves pregnant to consult their doctor immediately, not wait until later in pregnancy, but put themselves under a careful, competent physician at once, and he should on the slightest provocation make a thorough examination, and by so doing he may be able to detect fairly early, ectopic pregnancy.

I would like to close with the statement of Dr. Werth, who says that every case of ectopic pregnancy in its early stages should be considered in the light of a malignant affection and treated in the same manner that we treat a malignant growth, namely, by extirpation.

In treating gonorrheal complications or sequelae by means of vaccines, bear in mind that, as a rule, autogenous vaccines are of much more value than stock vaccines.

COUNTY SOCIETY REPORTS

Boone—The Boone County Medical Society met with O. E. Senour, of Union, on December 20th, 1911. It being regular election of officers, the following were elected for 1912:

President, B. K. Menefee; Vice President, O. E. Senour; Secretary-Treasurer, F. L. Peddicord; Delegate, L. C. Hafer; Censors, Drs. Slater, Rankin and Nunnelley.

C. G. Crisler, of Cincinnati, was elected an honorary member.

There being no further business the program was taken up.

L. C. Hafer read a paper on "Epidemic Poliomyelitis."

C. G. Crisler read a paper on "Elephantiasis" and presented a specimen of scrotum he had removed weighing six pounds.

After discussion supper was served, after which the meeting was adjourned to meet with L. C. Hafer, of Florence, on the 17th of January, 1912.

F. L. PEDDICORD, Secretary.

Clark—I have the following report to make from Clarke county. The Clark County Medical Society met at the court-house on January 16th, when the following officers were elected for the year 1912: President, Ernest Cole; Vice President, J. F. Lockhart; Secretary-Treasurer, D. H. McKinley; Delegate, C. G. Stephenson. Resolutions were adopted protesting against the repeal of the Vital Statistics Law, and against the passage of the Optometry Bill, and House Bill No. 74. After the business session the society adjourned to the "Tea Room" where an elegant four course dinner was served.

D. H. McKINLEY, Secretary.

Calloway—The Calloway County Medical Society held its first meeting for the new year on January 11th, 1912, and the attendance and interest were fine. The outlook is good. The society changed its day of meeting from the second to the first Wednesday of each month, that it would not conflict with Marshall County's meeting. Some doctors want to attend both.

W. H. GRAVES, Secretary.

Fayette—A meeting of the Fayette County Medical Society, the first of the year, was held last night at 120 Upper Street, at which the new officers were installed and a number of resolutions adopted, among them being one relating to the violation of a section of the Principles of Medical Ethics, which have been adopted by the American Medical Association, with which the Fayette Society is affiliated.

A resolution was also introduced and adopted declaring the Society's endorsement of the action taken by the county and city board of health in regard to the tuberculin test for dairy cows.

The following officers were installed: C. W. Trapp, President; Josephine Hune, Vice President; L. C. Redmon, Secretary; B. L. Coleman, Treasurer; W. O. Bullock, Censor, and C. A. Vance, Delegate to the State Medical Association.

Papers were read by B. A. Cockrell, on "Scarlet Fever" and by T. C. Holloway, on "Some Incongruous Remarks," while a number of others joined in the discussion.

The following resolution was adopted:

"Whereas, The American Medical Association has adopted certain principles of Medical Ethics, Section 4, Art. 6, of which reads as follows: 'It is derogatory to professional character for physicians to pay or offer to pay commissions to any person whomsoever, who may recommend to them patients requiring general or special treatment or a surgical operation. It is equally derogatory to professional character for physicians to solicit and to receive commission; and

"Whereas, The Fayette County Medical Society by its act of affiliation with the American Medical Association has adopted said principles of Medical Ethics with the force and effect of organized law operative during the continuance of such affiliation; and

"Whereas, The statement is made in the public and professional prints and confirmed by general report that said Section 4, Art. 6, of the principles of Medical Ethics is being violated by members of the medical profession,

"Therefore, Be it Resolved, That the Fayette County Medical Society hereby especially reaffirm said Section 4, Art. 6, of the Principles of Medical Ethics as a part of the law, governing its organization, and declares that any member who shall violate same shall be expelled from membership upon conviction by the censors, and that such act and cause thereof shall be given the widest possible publicity."

L. C. REDMON, Secretary.

Fleming—The Fleming County Medical Society met in Flemingsburg, December 20, 1911, and elected officers for 1912, as follows: President, Chas. W. Aitken; Vice President, J. C. S. Brice; Secretary Treasurer, J. B. O'Bannon; Assistant, T. B. Vice; Censors, T. B. Vice, one year; J. C. S. Brice, two years; Chas. Aitken, three years; Delegate State Society, C. R. Garr; Alternate, the whole push. We have been somewhat negligent in the past, but things look bright for bigger and better service in the future.

J. B. O'BANNON, Secretary.

Kentucky Midland—The Kentucky Midland Medical Society at its sixty-fourth quarterly meeting elected the following officers:

President, C. G. Daugherty, Paris.

Vice President, Lee Collins Redmon, Lexington.

Secretary-Treasurer, Chas. C. Garr, Lexington.

A number of new members were added to the

roll, among them being A. H. Keller and J. T. Brown, of Paris.

The next meeting will be held in Georgetown, on April 11th. Drs. Barlow, of Georgetown; Barkley and Sprague, of Lexington, O'Connor, of Louisville, are on for papers and Ussery, of Paris, Reynolds, of Frankfort, Bradley, of Lexington, and Knox, of Georgetown, are on for discussion.

The society passed resolutions affirming their allegiance to the principles of medical ethics of the American Medical Association and refused to admit or allow retention of membership in the case of anyone found guilty of splitting fees. The society also passed important resolutions, due notice of which will appear in *The Herald*, leader and local papers.

Among those present from a distance were Drs. Stuckey, Redmun, Estill, Vance, VanMeter, Lewis, Garr, Holloway, Willmoth, Cockrell, of Lexington; Parker and McCauley, Versailles; Reynolds, Frankfort; Louis Frank and J. T. Windell, of Louisville.

C. C. GARR, Secretary.

Muldrough Hill—Meeting called to order by President Ed. Smith at 10:30 a. m., in the City Hall, about thirty members being present.

On Motion, the reading of the minutes was dispensed with.

A. D. Willmoth made a motion that the society go on record as opposing the proposed Optometry Legislation and that each member use his influence in opposing it.

On motion, a committee of Drs. And, McChord and Dugan was appointed to visit Dr. Bowen, who is very ill and present the respects of the society.

R. A. Bates, Shepherdsville, reported verbally several interesting cases of Volkman's contracture following fracture of the arm.

O. Z. And made a motion that all visitors be accorded the privilege of the floor. Carried.

F. T. Fort, Louisville, discussed Dr. Bates' report and reported one of his own. Thought it had surgery to apply Plaster of Paris at once as tight bandages are the cause of these conditions. In his case he shortened the bones of the arm and greatly improved the condition.

W. C. Dugan in discussing Dr. Bates' report took issue with Dr. Fort and thought it did not result from the splint but was a trophic disturbance. In the early stages a great deal can be accomplished by galvanism and massage. In old stages one must shorten the bones or lengthen the tendons.

F. T. Fort explained that he had used electricity for nearly a year without results.

A. D. Willmoth spoke of the necessity of being guarded in remarks for fear of medico-legal complications. That one should be careful of ascribing such cases to a tight bandage.

C. Z. Aud, as counselor, spoke of the medico-legal aspects of the case and spoke of the neces-

sity of being guarded in remarks to patients and to uphold each other in such cases.

R. A. Bates in closing thanked the members for the discussion and for the assurance that such cases are not due to a tight bandage but a trophic disturbance.

A. D. Willmoth reported, first, a large lipoma with unusual features and showed pictures.

Second, Hydatid Cyst of Liver.

Third, Cholecystitis Following Typhoid.

W. C. Dugan, in discussing Dr. Willmoth's cases, reported a case where the tumor sprung from the serotum and extended below the knees. Agreed with Dr. Willmoth that he proceeded properly in the case of hydatid cyst and that it was a mistake to attempt to enucleate them.

He thought in cases of cholecystitis with typhoid one should operate in any case despite the fact that the cases seem nearly moribund and that the general practitioner and surgeon should be constantly associated together in order to prevent such cases or see them in the earliest stages.

A. D. Willmoth, in closing, spoke of the giving of urotropin in such cases and found that these cases occurred in spite of its administration.

Herbert Brunner, of Louisville, read a paper on "The Use of Vaccines in the Treatment of Genito Urinary Conditions."

On motion, discussion was deferred till after dinner.

On being called to order after dinner, Dr. Wathen moved that Dr. McChord's paper, being similar to Dr. Brunner's, be read first and the two discussed together. Carried. Before Dr. McChord read his paper Dr. Aud made the report of the committee sent to visit Dr. Bowen who said that he doctor appreciated the visit and sent his love to the society.

C. Z. Aud complimented Dr. Bruner on his paper and thanked him for coming before the society with such a plain and logical exposition of the subject.

O. H. McChord spoke of the cases that were not wholly surgical and not amenable to drugs either, where the vaccines filled a long felt want. Do not have to test opsonic index but rely on physical condition of the patient.

Congratulated Dr. Brunner on his splendid paper.

J. R. Wathen spoke of the triumph of bacteriology in vaccine treatment. Has proved the value of bacteriology. Doesn't believe in indiscriminate dosing with vaccines but cases should be selected. Not favorable in acute cases but the greatest benefit is obtained in the chronic cases.

Cases should be in the hands of men especially equipped for such work.

F. T. Fort and **W. C. Dugan** both endorsed the views of the essayist and thanked him for his paper.

Herbert Brunner in closing, emphasized the

fact that it is not necessary to take the opsonic index in chronic cases.

We do not use vaccines in acute cases because a temporary lowering of the index with a bacteremia might prove fatal.

J. R. Wathen, of Louisville, read a paper on "The Factors that Contribute to the Success in Modern Surgery."

Motion to have as many papers read as possible so that members who had to leave on the I. C., might hear them. Carried.

Guy Grigsby read a paper on "The Treatment of Fractures of the Long Bones."

C. H. McChord opened the discussion of the papers of Drs. Wathen and Grigsby. Thought Dr. Wathen's position well taken and that it was criminal to run patients into a hospital and operate without any preparation. If one expects to get good results in surgery one must give the patients the proper preparation.

Regarding Dr. Grigsby's paper he condemned the unnecessary manipulation of parts to elicit crepitus and putting old patients under a general anaesthetic to establish a diagnosis.

Thought the open treatment was proper and should be used more frequently and it would materially reduce bad results. Also of value in cases of delayed union with interposition of fragments, etc.

Process of repair much slower in ununited cases than in recent ones.

One must put on a firm fixed dressing in order to get good results.

One must have good hospital facilities to get good results.

C. T. Riggs seconded the remarks of Dr. McChord about manipulating the fractures and anaesthetizing old people.

In such cases he thought these cases should be treated for their general condition but otherwise left alone.

Reported several cases in support of such treatment.

G. C. Hall supported the position taken by Dr. Wathen regarding the proper preparation of patients and the undesirability of doing "rush surgery." Thought the general practitioner could adopt certain measures such as thorough cleansing of the bowels and the giving of calomel before the patient left home that would materially shorten the time of preparation at the hospital. In this manner the practitioner and surgeon could work hand in hand to the greater benefit of the patient.

B. J. O'Connor asked Dr. Grigsby if silver wire was not much used?

Ed Smith spoke of the loss of function with eversion as diagnostic of fracture of the neck of the femur and did not look for much shortening at first. Didn't believe in much dressing or apparatus but thought the best treatment was to look after the general conditions and get them up on crutches as soon as possible.

C. H. McChord spoke of the fallacy of not getting bony union in intra-capsular fracture and that it did occur. Didn't believe in letting patients go without any treatment.

Ed Smith maintained that bony union did not occur.

E. J. Strickler, Jr., spoke of the necessity of being properly equipped for doing such work.

Guy Grigsby, in closing, spoke to the point that Dr. McChord made and agreed that manipulation may be harmful and crepitus unimportant. Also that shortening was not at once evident. He advocated plaster dressing in cases in old people in intracapsular fractures and such cases were more comfortable under such conditions. Success depends upon not handling the wound with the hands in open work.

Thought also that plaster was highly important and resented any criticism of its use and that poor results in such cases were due to faulty application. Thanked the society for the kind reception of his paper.

J. H. Hester, of Manfordsville, read a paper on "How to Prevent Tuberculosis."

Bernard Asman opened the discussion of Dr. Hester's paper. In speaking of prevention showed the importance of each individual maintaining his own vitality. Not allowing apparently little things to become grave by neglect. Illustrated the cases occurring around the anal region.

S. N. Willis advocated the teaching of hygiene to teachers and the importance of the teachers being physically O. K.

C. T. Riggs advocated physical examination for both teachers and children and systematic examination of the pupils.

C. H. McChord spoke of the joint troubles in children and thought it due to the bovine tuberculosis from impure milk. Doctors should stand by the health authorities in demanding the testing of all dairy herds and cattle.

J. H. Hester was called to the telephone and did not get a chance to close his paper.

This completing the program the president called for volunteer case reports and a number of members responded, the society being entertained for a considerable time with this informal discussion.

Just before adjournment the following were elected to membership in the society: H. Bronner, B. Asman, Guy Grigsby, Louisville; Chas. H. McChord, Lebanon.

The society then adjourned to meet again in April.

The attendance at the meetings is steadily increasing. Notwithstanding the weather (and a worse day could hardly have been imagined), we had a full and enthusiastic meeting.

Those who were detained this time should be sure and be present at the April meeting.

GAYLORD C. HALL, Secretary.

Mercer—The Mercer County Medical Society

in regular session assembled at the usual hour and place. Members present: Witherspoon, Meredith, VanArsdall, Seay, Rogers, Powell, Strader, C. P. and J. Tom Price.

Neither the President or Vice President being present at the opening of the meeting W. H. Witherspoon was made temporary chairman. The minutes of the previous meeting were read and approved. No papers or clinical cases were presented as this was the regular annual business meeting and the time for the election of officers.

J. Tom Price reported that only one hundred and fifty dollars, so far, had been pledged for the purpose of equipping the operating room in the new hospital. On motion made and carried the chair appointed C. P. Price, C. B. VanArsdall, T. O. Meredith, the President and the Secretary a committee to collect the funds already pledged, and to secure additional funds, if possible, with authority to expend the same for the equipment of the aforesaid operating room in any manner agreed upon by the said Committee.

The election of officers resulted as follows:

President, M. L. Forsythe; Vice President, M. H. Southerland; Secretary-Treasurer, J. Tom Price; Censor for three years, E. L. Strader; Delegate for two years, J. Tom Price.

The following resolution was passed by the unanimous vote of the society, to-wit:

"Whereas it is the intention of certain refracting opticians to introduce a bill at the coming legislature creating a board of optometry and issuing a State license by such board,

"Whereas this would empower men not duly qualified to pass upon the state of a person's eyes, which has resulted in other states which have such laws, in the loss of eyesight as a result of such misdirected efforts, and,

"Whereas such persons are unfitted to make such examinations and assume such responsibility, by reason of their lack of training, be it resolved that we, the Members of the Mercer County Medical Society, unreservedly condemn such legislation as pernicious and harmful to the welfare of the general public as well as violating the spirit, if not the letter, of the already existing Medical Practice Act, and that we earnestly petition our Representatives in the Legislature to oppose such attempted legislation for the reasons set down above."

The society adjourned to repair to the New Era Restaurant for refreshments, oysters, etc.

J. TOM PRICE, Secretary.

Pulaski—The Pulaski County Medical Society held its regular meeting at the office of S. F. Parker to-day, our society meets the second Thursday in each month, on account of the unfavorable weather our attendance was small, only five being present. Several interesting clinical cases were reported.

S. F. Parker reported a case of fracture of the thigh at the junction of the upper and middle

third in a man 72 years old, the location of a fracture at this point on a man of that age being very unusual. Another peculiar feature of the case is the occurrence of traumatic delirium as a result of a man taking only two or three ordinary drinks of brandy daily, sometimes not more than one, the patient never drank to an excess. Dr. Parker also read a paper on adenoids, which was discussed.

Our study club is in a healthy condition, and meets each Monday night, doing the regular post-graduate work as outlined by the American Medical Association.

A. W. CAIN, Secretary.

Russell—The twenty-second annual meeting of Russell County Medical Society, was held in the parlors of the Holt Hotel, Jamestown, December 30th, 1911.

The President, L. D. Hammond, called the meeting to order.

Reading of minutes of last meeting was dispensed with.

Next was the election of officers for 1912: L. D. Hammond was re-elected President; J. B. Tartar, Vice President; J. M. Blair, Secretary; John D. Combest, Russell Springs, J. B. Scholl, Jabez, and W. G. D. Flanagan, Jamestown, were elected Censors for 1912.

The heavy rain prevented several of the country physicians from being present; that is if they had a hankering to be present. Hope we will have a prosperous year for the State society and for the county also and that every doctor in Russell county will join and keep up his dues.

J. B. SCHOLL, Secretary.

Rowan—The Rowan County Medical Society met at A. E. C. Evan's office in Farmers, with President A. Seaggs presiding.

Members present were T. A. E. Evans, A. Seaggs and A. W. McCleese and J. B. Messer, of Freestone, a visitor.

The Secretary, G. C. Nickel being absent, A. W. McCleese was appointed secretary pro tem.

This being the last meeting of the year, the election of officers for the coming year was declared in order and A. E. C. Evans was elected President; A. Seaggs, Secretary; A. L. Blair, Vice President, and T. A. E. Evans, A. L. Blair and A. W. McCleese were elected Censors.

It was moved, seconded and carried that, as there is a vacancy on the State Board of Health to occur and that our beloved brother A. E. C. Evans has been recommended by his State Medical Society to be appointed by the Governor; that the secretary-elect be instructed to draft resolutions, a copy of which is to be sent to the Governor recommending the appointment of Dr. Evans to that place.

T. A. E. Evans delivered an interesting discussion of the hookworm.

J. M. Messer, of Freestone, farther discussed

the subject and gave an elaborate account of an illustrated lecture on "Hookworm Disease" by L. H. South, State Bacteriologist, which he had recently attended in Louisville, which was very interesting and instructive.

A. W. McCleese gave an interesting talk on "Pellagra."

A discussion of "Placenta Previa" was entered into by the Society, (a number being present who had a case under observation.)

J. B. Messer, who had just been before the State Board for examination, whom we hope will soon be eligible to membership in our society, was invited to attend our meeting in the future, as he helped out in the discussion adding much to the life and instructiveness of our meeting.

The next meeting was appointed to be held at the office of Dr. Blair, in Morehead, January 24, 1912, at which meeting the payment of dues is to be made a special feature.

A. W. McCLEESE, Secretary.

Washington—The Washington County Medical Society met in Springfield on January 10th, with the following physicians present: W. W. Ray, M. W. Hyatt, W. E. Crume, W. S. Gabhart and J. H. Hopper. President W. E. Crume was in the chair. The minutes of the December meeting were read and approved with a slight correction. After regular business **M. W. Hyatt** read a paper entitled "The Early Diagnosis of Phthisis Pulmonalis." This was one of the very best papers ever read before this society and was discussed by **W. W. Ray**, **Hopper**, **Gabhart** and **Crume**, and in closing by **M. W. Hyatt**, who mentioned two cases by way of illustration. Several of the out of town physicians spoke of the needs of the laity for more enlightenment on the subject of tuberculosis before they would be able to reach a large per cent. of these early cases.

A. Y. Hatchett, who was on the program for a case report, received a very urgent call and had to leave town.

W. E. Crume reported a case verbally which was very interesting as the course and diagnosis being doubtful. This ended the regular program but **M. W. Hyatt** asked to be heard and in behalf of the society presented the secretary, in a neat little speech, with a very fine fountain pen. The secretary recovered from his surprise in time to express his very great appreciation of so useful a present.

The meeting was then adjourned.

J. H. HOPPER, Secretary.

Distressing urinary symptoms in bladder tuberculosis are fairly presumptive evidence of mixed infection, due to instruments or other agents.

The cancerous prostate is immovably fixed in the pelvis by reason of the extension of the malignant process into adjacent tissues.

THE FORUM

I write you for information regarding the mosquito and malaria. I note that some of our late authors take the position that the mosquito is the sole cause of malaria. Now since we have had such a great army of mosquitoes, in fact almost ten times more than for years and so little protection from their deadly bill and have suffered almost unbearable pain from their bites, as well as the mental pangs that we have endured thinking of the rattling of our dry bones that should take place when that awful ague chilled our frame, the unbearable headache and burning fever, etc., that was soon and so sure to follow, imagine our surprise at this late date, November 16th, and almost no chills, no malarial fever scarcely at all. The healthiest summer and fall that we have had for years. We had a dry May and June, but July and August were fairly seasonable. Can it be that the dry hot weather weakened the poison of the mosquito, or what is the matter and when shall we expect results. I am anxious to know. Hurriedly and timidly.

A. P. HENDLEY.

BOOK REVIEWS

Hospital Management—A hand-book for Hospital Trustees, Superintendents, Training School Principals, Physicians, and all who are actively engaged in promoting hospital work. By Charlotte A. Aikens, Author of "Hospital Training-School Methods and the Head Nurse;" "Primary Studies for Nurses;" "Clinical Studies for Nurses." 12mo. of 488 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1911. Cloth, \$3.00 net.

This is just the work hospital superintendents, training-school principles, physicians, and all who are actively interested in hospital administration have long wanted. It is a work with practical as its keynote. It presents the subject in the light of the most recent advances along the lines of modern hospital construction and management. Each chapter has been written by one specially fitted to write upon that particular phase of the subject; and Miss Aikens, herself a contributor, has shown great editorial ability in the arrangement of the several subjects treated. Every phase of hospital management is taken up and illustrated most profusely. Some of the most important chapters are: The Superintendent, the Medical Service of a Hospital, the Furnishing of a 100-Bed Hospital, Hospital Incomes and Management of Trust Funds, Hospital Book-keeping, the Hospital Store, the Kitchen, the Laundry, Surgical Supplies, Drug Room, the Training-school, Out-patient Department, and Laboratory. As a book on hospital economics it has no equal.

SOMEWHAT PERSONAL

To the Medical Profession of Kentucky, Greeting:

I am just in from Frankfort and it swells my heart with pride to be able to assure you in full confidence not only that we will win our fight on every point, but that expressions from senators and representatives on every hand convince me that no previous General Assembly has ever so readily recognized the far-reaching character, magnitude and unselfishness of the work which the rank and file of our profession are doing every day to protect the health, lives and homes of the people, and to make living better worth while.

As is now well known to both legislators and the profession, the attack on us had its origin in the pique of one man, a good fellow, by the way, who should not be censured for exaggerating his own importance and grievances and in mistaking the remedy for the latter, and would have attracted little attention except for the dissatisfaction which had arisen in the first weeks of the operation of the vital statistics law in a few country districts.. This was remedied by a very simple amendment, but before this could be worked out and explained the League of Medical Freedom, the vast interests engaged in poisoning and robbing the people by the manufacture and sale of adulterated foods and drugs, Charley White Moon and other fake and quack combinations in and out of the State got into the fray and deluged the desks and waste baskets of legislators with the class of literature with which all are so

familiar from its use in these fights against Dr. Wiley, Senator Owen and the National Department of Health, school inspection, vaccination and all similar efforts to protect the public health, but so filled with abuse and misrepresentation as to be its own best antidote.

No other state in the Union has such a profession as ours, and I have never before been so proud to represent you. Knowing from the outset the disreputable forces which would get behind the movement, I realized that the attack could not long remain personal but would turn upon the profession and the excellent system of laws you have secured by years of patient, persistent effort. And most nobly did you and the intelligent people of all classes respond to the onslaught. Not only were the societies and profession in almost every county active, but the Federation of Women's Clubs, Boards of Trade, Teachers and Farmers' Institutes, and leading citizens in every section were equally so.. I wish you could read the thousands of telegrams and letters which came spontaneously from the most unexpected sources outside of the profession and could have seen the scores of jurists and other leaders of public opinion who came in person with proffers of help.

It was worth all the time and inconvenience and, one and all, I thank you from the bottom of a heart which will always beat as true to you as yours does to me.

J. N. McCORMACK.

STATE BOARD INVESTIGATION

Acting under the unanimous instructions of your Council, as the spokesman of the Kentucky State Medical Association and the defender of the 3334 registered, practicing physicians of Kentucky, your Secretary submitted the following proposition to the Committee on Kentucky Statutes of the General Assembly of Kentucky before which Mr. Herrington, the Representative from Madison County, has been investigating the State Board of Health:

"Gentlemen, you have seen our JOURNAL. It reaches every doctor in Kentucky. I am requested by our Council to ask that you instruct your stenographer that every question and answer asked here be faithfully transcribed, and that we be given a copy, and, without expense to the public treasury, we will print an edition which will reach every nook and corner of the grand old Commonwealth, and we will ask that if there be any man, woman or child who has aught to add to this investigation that will show any fault in our health or medical laws or any way by which more lives can be saved, that he speak now. We will get the edition out at once, Mr. Chairman, so that you may hear what you can while the General Assembly is yet in session. If there were anything wrong, Mr. Chairman, the Association of which I am proud to be spokesman, would have known it and would have demanded of you that it be righted. All we now ask is that you expose the motives of the few small men who instigated this investigation, that you know everything worth knowing about our work and our relations with our profession and the people, and that you then make such a report as will continue for us the confidence and moral support of the General Assembly."

The impression created through the newspapers by Mr. Herrington has been that this is an investigation ordered by the Legislature. The facts are as follows: Mr. Herrington has introduced a bill, House Bill No. 74, which repeals that part of the present law which empowers the Governor to select the members of the State Board of Health from lists of three nominations selected by the various state societies for each vacancy. This law if passed, would restore the status before the present law was enacted in 1904, when appointments on the State Board were frequently made as rewards for personal or partisan services. No other body is so well qualified to

select health officials as the state medical societies of the various schools and this law has the approval of practically every physician in Kentucky as well as of every informed publicist and layman.

Upon Mr. Herrington's request this bill was referred to the Committee on Kentucky Statutes one of the busiest committees in the House, and they have been able to devote such short hours to the hearing that to those interested it has seemed to drag along almost interminably.

On the same day Mr. Herrington offered a resolution empowering any committee to place persons under oath and subpoena witnesses about any bill. Under this omnibus authority he had the following subpoena issued:

"THE COMMONWEALTH OF KENTUCKY.

"To the Sargeant at Arms of the House of Representatives, Greeting:

"I command you to summon Dr. T. R. Moore, of Frankfort, Kentucky; Dr. Lillian H. South, of Bowling Green, Kentucky; Dr. J. N. McCormack, of Bowling Green, Kentucky; Dr. A. T. McCormack, of Bowling Green, Kentucky; Dr. J. C. Mitchell, 1200 West Market Street, Louisville, Kentucky; Dr. C. W. Kavanaugh, Lawrenceburg, Kentucky; A. J. Parlin, Lawrenceburg, Kentucky; W. F. Lillard, Lawrenceburg, Kentucky; Dr. H. S. Kellar, Frankfort, Kentucky; Dr. John South, Frankfort, Kentucky; Judge J. H. Polsgrove, Frankfort, Kentucky, to appear before the Committee on Kentucky Statutes of the House of Representatives of Kentucky, at the parlor of the Capital Hotel in Frankfort, Kentucky, at eight (8) o'clock P. M., on Thursday the 25th day of January, 1912, to answer, under oath, any questions that may be propounded to them on any matter, which is deemed by said Committee to be a subject of proper inquiry, regarding its consideration of House Bills Nos. 74 and 93, which are now pending before said Committee, and to warn each and all of said witnesses that upon their failure to appear, they will be cited for contempt of the orders of the House of Representatives of Kentucky, and the Sargeant at Arms will make due return of this summons to me.

"Witness Harry A. Schoberth, Chairman of Committee on Kentucky Statutes, at the Capital, Frankfort, Kentucky, this 19th day of January, 1912.

"H. A. SCHOBERTH,

"Chairman."

A systematic campaign was begun through the public press charging that our entire Association and its splendid work were but the corrupt creature and political machine of Dr. J. N. McCormack, whose honorable career from 1883 in the service of the profession and people of Kentucky was rewarded by the charge from Mr. Herrington that he was "the smoothest, most plausible, most persuasive and at the same time, most powerful lobbyist ever known." He needs no defense to the physicians of Kentucky nor of the United States.

Of the witnesses summoned at Mr. Herrington's instance, only Drs. J. N. McCormack, John G. South, Lillian H. South, A. T. McCormack, J. C. Mitchell, John G. South and H. S. Keller have been examined.

It was held by the Chairman of the Committee that the burden was upon the State Board of Health to show that it had conducted itself properly. Every one was excluded from the room but newspaper men and the members of the Legislature. This is our only excuse for presenting to the profession this incomplete statement of what occurred in the Committee room. It is all taken from the newspapers. They quite naturally give most notice to the scraps while we are most interested in the facts. The following is the fullest account by the veteran reporter, Will S. Kaltenbacher, in the Louisville Times:

REVIEWS LIFE WORK ON WITNESS STAND

**Dr. J. N. McCormack, Secretary of
State Board of Health Testifies
Before House Committee On
Kentucky Statutes.**

Denounces Effort to Inject Politics

(By Will S. Kaltenbacher.)

Frankfort, Ky., Jan. 25.—Three witnesses were examined at the meeting of the House Committee on Kentucky Statutes which met in the parlor of the Capital Hotel last night to give a hearing on the Herrington bill providing for a change in the appointment of the members of the State Board of Health and placing them in the hands of the Governor. The witnesses heard were Dr. J. N. McCormack, of Bowling Green, secretary of the State Board of Health; Dr. D. M. Griffith, of Owensboro, and Dr. L. S. McMurtry, of Louisville. The meeting lasted from 8 until 1:30 o'clock, all per-

sons being excluded except the members of the Legislature and newspaper men.

The Committee on Kentucky Statutes is made up as follows: H. A. Schoberth, chairman; B. S. Wilson, W. V. Perry, S. F. Reed, J. A. Polin, J. W. Holland, W. A. Price, M. C. Kirk and W. S. Smith. It is planned to resume the hearing this afternoon. Dr. Lillian South, the State Bacteriologist, was allowed to file a statement and will be cross-examined to-day.

Makes Strong Witness.

It was conceded on all sides that Dr. McCormack, who has been at the head of the State Board of Health work for over thirty years, made a strong and most convincing witness for his side of the question. He produced all the records of the State Board of Health since its establishment thirty-three years ago and gave an exhaustive account of what had been accomplished in this time. Dr. McCormack denounced the efforts to place the State Board of Health back into a political atmosphere and declared he had always strived to keep the body divorced from politics and had succeeded under the present law. Dr. McCormack resented some of the questions propounded to him, especially one asking him had he ever "lobbied" with the Legislature in the interest of the railroads or other interests. He replied that "there were some questions no gentleman should ask and no gentleman should answer."

Vital Statistics Law.

Dr. McCormack strongly defended the vital statistics law passed at the last session of the Legislature. He said the State Board of Health now had the record of 63,000 births and 32,000 deaths in Kentucky during 1911, and that these and subsequent records would prove of incalculable benefit in reducing the number of preventable deaths. He said the law was not yet fully understood.

Dr. McMurtry and Dr. Griffith supported Dr. McCormack in their evidence and paid him high tribute for his work as a health expert. Both declared that Dr. McCormack had never attempted to dominate either the State Board of Health or the State Medical Association.

Dr. J. N. McCormack's statement will be found elsewhere in this issue.

Mr. Dunlap, in the Frankfort News-Journal gives the following account of this first session:

QUESTION STIRS IRE

Dr. J. N. McCormack in Tilt With Representative Herrington.

AT THE HEALTH PROBE

Secretary Resents Insinuation That He Worked For Railroads.

Investigation by House Committee Draws Many Physicians To Frankfort For the Day.

Investigation of the Kentucky State Board of Health, which was begun last night in the parlor of the Capital Hotel, by the House Committee on Kentucky Statutes, was marked by a tilt between Representative L. B. Herrington and Dr. J. N. McCormack, Secretary of the Board of Health. Dr. McCormack resented what he took to be an insinuation that he had "lobbied" for the railroads, while in Frankfort in the interests of measures affecting the Board of Health.

Dr. McCormack was on the witness stand and was being examined by Mr. Herrington, who had asked a large number of questions relating to Dr. McCormack's absence from Kentucky while acting as secretary of the Board.

"Do you ride on a pass, Doctor?" asked Mr. Herrington.

"I do, sir."

"On what roads?" asked Mr. Herrington.

"On all that will give me passes. I save the State just that much money by riding on passes."

"Do you use a Pullman pass?" Mr. Herrington asked.

"I do, and that is that much money saved to the State."

Investigate Cars.

Mr. Herrington then asked if it was not a fact that, as executive officer of the Health Board, it was his duty to investigate Pullman and

railroad cars. Dr. McCormack explained that it was his duty, and that the railroads were forced to do more in this than in any other State, the Kentucky Board making the first move to require disinfection of all cars.

"Did you ever perform any service for the railroads while you were here in Frankfort in the interest of the Health Board?" asked Mr. Herrington.

Dr. McCormack grew angry, as was shown by his face, and said:

"Never, sir. That is an insinuation that I will not permit."

Harry Schoberth, chairman of the committee, said that no personalities would be permitted in the committee meeting. Dr. McCormack said:

"I did not start the personalities, but I will not permit some questions to be asked."

Judge Lewis McQuown, attorney for Dr. McCormack, then objected to the line of questions that was being asked, stating that he thought them irrelevant and improper. Mr. Herrington then explained that he had meant no offense by his question, and was merely trying to get at the facts as quickly and simply as possible. The incident then ended, and Mr. Herrington continued his questions.

On Stand Long.

Dr. McCormack was on the stand for several hours, and answered a large number of questions on various subjects pertaining to the methods of the State Board of Health in the keeping of accounts and in the management of its affairs. He said money was paid out on vouchers which were issued by him, countersigned by the President. Dr. McCormack stated, in answer to questions, that during most of the thirty years that he has been coming to Frankfort during sessions of the Legislature, he has paid his own expenses, but since 1900 the Board has been paying these expenses. The vital statistics act was gone into carefully.

The following version is that of Mr. Moss in the Cincinnati Enquirer:

BOTTOM**Falls Out of Quiz Into Conducting of Kentucky Health Board.****Secretary McCormack Is Placed on Grill.****Says He Gave Up Big Salary To Help State.****Frankfort Flooded With Physicians To Testify for Noted Doctor.**

Special Dispatch to the Enquirer.

Frankfort, Ky., Jan. 24.—In the presence of nearly one-half of the members of the General Assembly Dr. J. N. McCormack, of Bowling Green, Secretary-Treasurer of the State Board of Health, to-night testified before the probe committee of the House as to the manner in which he had conducted the affairs of his office since 1883.

He was charged by Representative L. B. Herrington, of Richmond, as being "the smoothest, most perfect machine to operate in this state." He also was accused of using his position to appoint members of his family to places of pecuniary profit; of controlling the State Board of Health, and dominating every County Board of Health of Kentucky.

Representative Herrington has a measure before the House to abolish the State Board of Health as it is now constituted, and provide for a Board of Health to be appointed at the discretion of the Governor. Physicians from every part of the State were here to testify for Dr. McCormack.

The meeting was held in executive session, except to the members of the Legislature and the press.

Looked Upon as Failure.

The effort of Representative Herrington was looked upon as a failure. Dr. McCormack testified that he had not taken any steps to arouse public sentiment in his favor since the probe resolution passed the House, and has in his evidence a protest against this investigation signed by 17 of the 22 physicians in Mr. Herrington's home county.

One of the features of the probe was the evidence of Dr. McCormack that he receives as his salary from the State but \$1,200, the same salary he pays his stenographer. Having

been a very fortunate business man, Dr. McCormack testified that he could afford to carry on the work independent of the salary he gets from the state.

He said he recently resigned the position of Organizer of the National Medical Association at a salary of \$6,000 a year in order to give all his time to health work in Kentucky, and, he said, "to save the babies, women and men of the state."

Mr. Herrington sought to show that as Organizer for the Medical Association, Dr. McCormack was a "lobbyist," asking frequently if he did not spend much of his time before Legislatures of other States, and if he was not more than one-third of his time in Washington when Congress was in session.

Defies His Accuser.

All of this Dr. McCormack denied, and defied Mr. Herrington or any person to produce evidence he is or ever had been a "lobbyist."

Dr. McCormack testified that he had written the laws and constitution for every state and every county medical association in the United States. Mr. Herrington asked if he did not ride on railroad passes, and when he received the answer from Dr. McCormack that he did, Mr. Herrington asked if he had helped railroads to put over favorable legislation.

Another question along this line would have required the presence of the Sargeant-at-Arms. Dr. McCormack said he rode on passes to save the State money. He testified that he had been elected to his position unanimously for 33 years.

Senator B. F. Tichenor, of Daviess county, said that 99 out of every 100 physicians in the State would come here to fight for Dr. McCormack if necessary. The purpose of the probe is to have repealed the vital statistics bill, calling for an annual appropriation of \$30,000, passed by the last Legislature.

Mr. Montgomery in The Louisville Herald gives the following account of the session of Jan. 30:

PRAISE FROM COLLEAGUE.**Dr. Keller Says McCormack Is an Efficient Officer.**

Frankfort, Ky., Jan. 30.—Dr. J. N. McCormack, of Bowling Green, Secretary of the State Board of

Health, to-day, was styled "the best health officer in the United States," by Dr. H. S. Keller, of Frankfort, who served on the board for four years. Dr. Keller made the statement while testifying before the subcommittee on Kentucky Statutes, which is trying to discover if Dr. McCormack has built up a machine within the board that he might perpetuate himself in office.

Only one other witness testified to-day. He was Judge B. C. Tarter, of Pulaski county, who told of the good work done by the county auxiliary. He declared the State Board of Health was free of politics.

Representative L. B. Herrington asked Dr. Keller if Dr. McCormack was a politician, "I should not classify him as such," was the reply. Asked if Dr. McCormack's efforts in securing legislation affecting public health had been effective the witness replied: "Best ever."

Dr. Keller said the secretary's authority over the State Board has been supreme until about a year ago when four members got together and decided to support him, not because of Dr. McCormack's having usurped that authority, but because the law specified that the responsibility of conducting the board's affairs rested with the full membership of the board. The hearing will be resumed to-morrow.

NOT ONE SINGLE MATERIAL STATEMENT HAS BEEN MADE BY ANY WITNESS WHICH WAS NOT A MATTER OF COMMON KNOWLEDGE TO EVERY PHYSICIAN OR OTHER PERSON IN KENTUCKY WHO HAS READ THIS JOURNAL AND THE REPORTS OF THE STATE BOARD OF HEALTH.

One medical witness has been produced by Mr. Herrington. This was Dr. J. C. Mitchell, of Louisville, who testified that he had been appointed on the State Board as an eclectic after the adjournment of the last session of the Legislature, and that Governor McCreary had displaced him and reappointed Dr. Geo. T. Fuller, of Mayfield.

The unanimity of the medical profession of the State has surprised no one but Mr. Herrington. His statements that the medical profession of Kentucky was or could be dominated by any one was the cause of great surprise to the physicians who heard of it.

Statements from 29 of the 35 registered physicians in Madison County, of which Richmond is the county seat, and where Mr. Herrington is said to live, is also printed under the head of Official Announcements.

VITAL STATISTICS AND OPTOMETRY LEGISLATION.

A crisis has arisen in the public health and medical organization movement in Kentucky. Under the thin disguise of an attack upon your officials, a dangerous fight is being made all along the line against every advance secured in thirty years by the profession in their fight for pure food and drugs and their warfare against disease. At the beginning of the session of the General Assembly a number of bills repealing the vital statistics law were introduced. These were, in the main, introduced by members who had come in contact with some defect in the law, and the honest opposition to this most important law has been met by a substitute for House Bill 28 and Senate Bill 34, prepared and originated by the Committees on Public Health and reported unanimously. This substitute provides for several deputies in the larger country registration districts, that undertakers, carpenters who make coffins and county officials may be made deputy registrars so that no funeral will be unnecessarily delayed, and that a burial permit may be issued in the country upon the filing of a promise to deliver a complete death certificate within five days from the date of death.

The second element in the attack is the so-called optometry bill, House Bill No. 90, which will make doctors out of spectacle vendors by act of the General Assembly quite regardless of training or fitness. This attack upon the medical law is nation wide and identical bills, prepared by some central syndicate have been met by vetoes by such Governors as O'Neal of Alabama, Wilson of New Jersey, Harmon of Ohio, and Deneen of Illinois.

Dr. J. M. Ray, of Louisville has an eye which he has recently removed for cancer, for the cure of which three different pairs of glasses were fitted by one of the men promoting this bill at \$25 per fit.

The fitting of glasses for errors of refraction without the use of drugs or medicines is a branch of the practice of medicine, and, in order to settle this question for all time to come the following has been prepared and will be offered as a substitute for the Optometry Bill:

"An Act to Amend an Act entitled 'An Act to Prevent Empiricism in this Commonwealth,' approved March 18, 1904.

"Be it Enacted by the General Assembly of the Commonwealth of Kentucky, that 'An act to prevent empiricism in this Commonwealth,' approved March 18, 1904, be and the same is hereby amended by the addition of the following section.

"Section 1. Any person offering to relieve errors of refraction or defects of eyesight in the human eye by the fitting of glasses without the use of drugs or medicines shall be known as an optician. The State Board of Health shall issue a certificate to any reputable optician who desires to practice in this State who has passed a successful examination before it in the branches of medicine as taught in reputable optical colleges, who shall possess a diploma from a reputable and legally chartered optical college in some state in this Union; and the State Board of Health shall, through one of its members or inspectors, examine any legally chartered optical college in this Union upon application of any interested citizen of this State, and, after due notice and hearing, decide whether said college is reputable, and such inspection and report may be repeated from time to time at the discretion of the Board; Provided that nothing in this section shall be construed to apply to persons licensed to practice medicine in this State, or to give to any optician or other person the right to attach the title M. D., surgeon, doctor, physician, oculist, ophthalmologist, eye specialist, doctor of refraction, doctor of ophthalmology, doctor of optometry, or any word or abbreviation to his name indicating that he is engaged in the treatment or diagnosis of diseases of, defects or injuries of the human eye, or to use drugs or medicines in any form for the treatment or examination of the human eye, or to use any therapeutic measures or agencies other than glasses for the treatment of the human eye."

The above amendment is really included in Section 7 of the present law, but this will make it clear, and it is so fair that there can be no objection raised to it by any educated optician, and its purpose is to protect the people only from those whose ignorance and lack of training endanger the eyesight of our people. The examination would be conducted as at present with the identity of the applicant unknown to the examiner who grades his papers, and a license issued after such an examination would be of real value to its holder as a voucher for his competency.

If every physician will make it plain to his Senator and Representative that the above substitutes will meet and settle real problems, the situation will soon clarify itself. So many bills have been introduced that it is essential that when you write, you ask support for the committee substitute for House Bill 28 and Senate Bill 34, which are the vital

statistics bills, and for the "State Board of Health Examination Substitute for House Bill 90." These bills will probably be voted upon this week and it is essential that every one act at once.

OFFICIAL ANNOUNCEMENTS

The following is from members of the Madison County Medical Society:

To Dr. J. N. McCormack, Greeting:

We, the undersigned physicians of Richmond and Madison County, wish to express our confidence in you personally, and our appreciation of your services to the Profession of the State and Nation, and, especially, do we condemn the action of our representative, Mr. Herrington, as being uncalled for and tending to bring discredit to the Profession and State.

MURISON DUNN,
T. J. TAYLOR,
H. G. SANDLIN,
R. H. COWLEY,
D. R. BOTKIN,
L. A. DAVIS,
A. H. BAKER,
ROBT. C. COOMER,
P. CORNELIUS,
J. H. RUTLEDGE,
J. W. SAMS,
C. J. BALES.

The following is a statement signed by 18 of the registered physicians who are not members of the Madison County Medical Society:

To Dr. J. N. McCormack, Greeting:

We the undersigned physicians of Madison County, Ky., have not in recent years been members of the Madison County Medical Society, for reasons well known by our profession and people, but we have nevertheless always been and shall continue to be interested in the protection of our people from the ravages of disease. We believe that the officials chosen to administer its health laws should, when their duties are faithfully discharged, receive the endorsement and support of the good citizens of this great Commonwealth. We well remember when you were with us a number of years ago in a small-pox epidemic, then prevailing in our midst, and recall how you so heroically fought this terrible disease, using your own money to help people who were afflicted with the disease. We know how you have uniformly discharged your duties all over the State, doing much to advance our profession and protect the health of the people, and we commend you in the highest terms for what you have done. The profession and people are deeply

indebted to you and have now and always have had the highest confidence in your integrity and honesty of purpose and we feel sure that a fair investigation into your motives and methods, at Frankfort, or elsewhere, will reflect credit on you and the entire profession, and will show that you are interested alone in the cause of the people. We deeply deplore the attack now being made on you at Frankfort and we repudiate this effort to cast reflection on such a worthy official as you have always shown yourself to be.

We desire to state emphatically that our representative does not reflect the wishes and feelings of our people and profession when he assails you as he has done at Frankfort within the last few days. We feel that he has been badly advised. Our people endorse you and everything you have done for many years past, in the discharge of your official duties. We have unshaken confidence in you.

DIGEST OF HEALTH BILLS.

The joint meeting of the Council and Legislative Committee of the Kentucky State Medical Association, after careful consideration, desire to call the attention of the medical profession and people of Kentucky to the following bills:

House Bill 74, putting the State Board of Health into politics is a bad bill and should be defeated.

House Bill 90, making doctors by statute out of spectacle dealers is ridiculous. As well make dentists of blacksmiths by law.

House Bill 28 and Senate Bill 34. The Health Committee in both House and Senate have reported a substitute for these bills which removes all the objectionable features of the Vital Statistics Law and retains all the valuable points. No funeral will be unnecessarily delayed unless crime is suspected. The substitute should pass.

House Bill 235 by Francis Douglas, of

Boyle County should pass. It is a good bill. It is an Act creating a commission to be known as Kentucky Board of Tuberculosis Commission, defining its powers, appropriating \$15,000 annually to be used by the board, and authorizing the establishment of districts, consisting of one or more counties, and authorizing and providing in such districts for the erection of a sanatorium for the treatment of tuberculosis, and further authorizing county and district taxation for the purpose of making an appropriation for the necessary land and erection of buildings, and an annual appropriation for the maintenance of such sanatorium.

Senate Bill 107, an Act, presented by Senator W. E. Dowling, of Anderson County, prohibiting the use of public drinking cups, is a good bill and should pass.

E. RAU, Chairman.

By Order of the Council,

STATEMENTS SUBMITTED

To the Committee on General Statutes of the General Assembly of Kentucky in the Investigation of the State Board of Health.

STATEMENT OF DR. J. N. McCORMACK.

Mr. Chairman and Gentlemen of the Committee:

In order to economize in time, with your permission, I present to you the minutes of the State Board of Health, showing its operations in detail from its creation over a generation ago to the last meeting held in this hotel on the 10th of the present month; the Treasurer's books and numbered vouchers for each item, accounting for every dollar appropriated and expended by the Board since I became its Secretary, October 1, 1883, and containing for each year a report of the committee appointed to audit the books and vouchers, certifying to their correctness at the bottom of each annual statement. These minutes and financial transactions have been published for each biennial period and widely distributed.

When the enlarged appropriation became effective January 1, 1911, after discussion with the Board, and conference with the present and former State Examiners, it was decided that the method of keeping the financial records could be improved and extended, and I present to you a full detailed, numbered statement of each expenditure under the appropriation of \$30,000, with a voucher-check receipt and itemized account corresponding to each entry, and indicating the department for which the expense was incurred, du-

plicates of these voucher-checks having been filed with the Auditor of Public Accounts, as required by law. Attached to this financial statement will be found the report of the Potter-Matlock Trust Company, employed to audit the books and vouchers, and that of the Auditing Committee of the Board appointed for the same purpose. All of these itemized statements and other matters will be embraced in the forthcoming volume of transactions and open to every citizen. In 1886 an appropriation of \$6,000 was made to stamp out pleuro-pneumonia in cattle. Only \$3,000 was drawn out, the Board stamped out the disease for \$2,480, \$520 was covered back into the Treasury and the other \$3,000 remains there available for a similar emergency. So in 1893 an emergency fund of \$10,000 was created against cholera, yellow fever or other exotic pestilence. Upon the approval of the Governor \$2,000 of this was used during the yellow fever epidemic of 1898, and \$8,000 remains in the Treasury to be used with the approval of the Governor if the State should be seriously threatened by any great epidemic disease.

In this connection it may be of interest for you to know that the Board was created upon the recommendation of Governor McCreary in 1878 to meet the emergency of an epidemic of yellow fever then raging in the south, and that, before the appropriation became available, with funds raised upon the personal credit of its members, who served then, as now, without compensation, it was in the field fighting to protect the health and lives of our people. For the first twenty-two years the total appropriation for the work was \$2,500, after which, until last year, it was \$5,000. During all these years the work of the Board has ranked well up with those of other states having five and ten times the funds. This was only possible because the members of this Board and 695 members of county and city boards of health served without compensation except for their executive offices and because I furnished the Board an office in my residence, with heat, light and janitor free of cost, as our hospital is now doing for one of the laboratories, and for years my wife and son, and in times of emergency, every servant in the household, assisted in the clerical and stenographic work, and in getting out the enormous mail, without any or at only a nominal cost. At different times when my son was away at college, Walker D. Hines, now at the head of the Sante Fe system, and McKenzie Moss, now Circuit Judge in my district, took his place in the morning and evening when not in school for ten dollars a month. For all these years my son and I, long before he was a doctor and since, were on the border where pestilence threatened from the south,

and in the counties in every section during smallpox and other epidemics, our overalls were covered with scabs and pus while we helped to carry the sick to the improvised hospitals and to bury the dead, a service which most of you would not render for all the revenues of Kentucky.

More unpleasant than all of these things, and because no one else would do it, I haunted these legislative halls year after year, often classed as a lobbyist by those who did not know any better, but most nobly supported by my profession in every school of practice, as I am now begging that authority be given my Board and profession to protect the people from pestilence and impure food, drugs and quackery, and so successfully that the laws on most of these subjects written by me, are used as models in other states.

At the outset, the State Board of Health was a purely political body, pull having more weight than fitness, and while excellent men personally, many of them had little training and often could not afford the time for its duties. One Governor went so far as to exact a pledge of each appointee that he would vote to put the health and lives of the people of Kentucky in the hands of one of his political friends, and only failed because this most worthy physician declined to accept the position when he knew what would be required of him. The county boards were then appointed by the fiscal courts and were little more than farces. All this became such a recognized evil that representatives of all schools of practice agreed upon and secured the passage of the present law, which put the selection of members upon a scientific basis, with the result that the men now composing the Board will bear favorable comparison with the Court of Appeals or any other body of men in the State. On account of his wisdom in public affairs, and the interest he has always taken in health matters, the present Governor could be safely trusted to make nominations on the Board without restrictions, but this was intended, and was agreed upon as a permanent provision, because sad experience has taught us that the average governor was no better qualified to select members of the Board than the average doctor would be to select judges of the highest courts, and that it would be just as reasonable to put such authority in his hands. The same principle applied to the appointments of county boards of health by the fiscal courts, and this will be realized when the people come to know that health and life and the officials who protect them are more important than property interests and the courts which look after them. The county boards are now selected upon merit alone. They serve without compensation and yet the spirit

of the profession is such that there has never been any trouble in getting the best men to serve. I hand you the lists of these boards for thirty years that you may study them and ascertain if they are men who could be dominated by any man, and that such an insinuation is a reflection only upon those who inspired it. To return to this vicious system, discarded because it was vicious, and put us back in the pool of politics would be a step backward which would and ought to be condemned by all right-thinking people who have no personal friend or end to serve, and I have no fear that it will ever be done.

When the \$30,000 appropriation was secured it was at once decided to try to do twice or thrice that amount of work with it. With this end in view competitive bids were secured on all laboratory and other equipment and supplies, much of the scientific apparatus coming from abroad duty free, often with a saving of 50 per cent or more. The heads of departments and employees were put upon minimum salaries and stimulated to do the best that was in them by promise of better compensation as soon as all the cost of equipment was paid. All of them have made good, and the bacteriological department has saved more to the people on diphtheria and rabie serums alone than its entire cost for the year, and without adverse legislation the good to come to the homes of our people from these activities is beyond computation. We have the best equipped laboratories in Kentucky for their purposes and scope, and I ask you to visit and inspect them, as the health committees of both houses have been asked to do.

A few men have tried to dominate Kentuckians, but no one has ever succeeded. I hold no office in the State Medical Association, and have not for twenty-eight years when I was its President, and my opinions have weight with my profession only because of what I have done for it. This hand has written every health and medical law on our statute books, and is in use as a text book in our normal and hundreds of district and high schools, and almost every health circular and leaflet. I led the organization movement in every county, pleading for and securing harmony where there had been discord, and bringing together all schools of practice. Completing the organization of my own State nine years ago, after consultation with the Board, and upon its advice that the Board's prestige, and my usefulness would be greatly increased thereby, I accepted the position as Chairman of the Committee on Organization and health lecturer of the American Medical Association for the United States, and, in that capacity, have inspected and spoken upon

health conditions in ever principal city and county in this country. In doing this my engagements were such that I only missed two meetings of the Board and could always be here should an epidemic occur. Upon the completion of the laboratories, the possibilities for good to our own people so impressed me that I resigned this position, with its salary of \$6,000, over the protest of the National Association, to devote the remainder of my active life to the improvement of health conditions in my native State, upon the same salary paid my stenographer, and which I have never asked to be increased in all these thirty years. Is it surprising that the profession are my friends, and that they consider an attack upon me as being made upon themselves? But it is charged that the profession is not for me. In order to put this to the test I now propose that if any state association, homeopathic, eclectic or osteopathic, or any county society, including Mr. Herrington's, and there is no better one, will ask it, I will join in the request for the referendum vote provided on all matters by our Constitution, and will cheerfully resign if 90 per cent. of all the doctors do not support my policies and work.

In conclusion, nearly thirty years ago, by a unanimous vote, I was made the executive officer of this Board, and this has been done at regular intervals since until two weeks ago, upon motion of the homeopathic member, seconded by his osteopathic colleague, I was again elected unanimously for a term of four years. In all these years my life has been an open book both to the profession and people, and I have done my duty to every interest as God gave me the capacity to see it. This is the first, and, with the fair and impartial hearing I know you will give, I expect to make it the last, time any man will ever question my motives, my capacity or my integrity. My respect for this Committee, my profession and for myself has kept me from trying this issue in the public press, as my traducers have attempted to do. Most of you are strangers to me, and, since the day this question assumed a personal phase, I have spoken to no one of you on the subject, greatly interested as I am in other bills before you, and have asked no assistance from any county board of health or physician, or written or inspired a letter to one of them. I do not need the pittance of a salary, ask no man's favor and would despise myself if I accepted any man's sympathy. I only court the full, fair investigation which I know you will give me and the Board, the standing of which has become almost as dear to me as my own, and then—justice.

STATEMENT OF D. M. GRIFFITH.

I was questioned in detail about the organization of the State Association particularly as to whether there was any politics in same and whether or not it was dominated by J. N. McCormack and being fully informed by virtue of yearly attendance at its meetings, I could conscientiously and truthfully state that politics was completely ousted by the reorganization that took place some ten or twelve years ago and that neither of the McCormacks had ever, at any time sought to influence my vote or any man with whom I was acquainted either for or against any man or any measure. I was also asked, after leaving the Winchester meeting, why I went back. I stated I was requested by 'phone or telegram to come. I was asked who made that request, I stated, which was true at the time, that I could not remember. I was asked if it was either of the McCormacks. I stated as before, that I did not know who it was. The expression upon Mr. Herrington's face rather indicated to my mind that he thought Dr. McCormack had wired me and I was trying to cover that fact. The truth was I did not remember. Since giving that testimony my memory is perfectly clear as to who did call me back; it was Dr. M. A. McDonald, of Whitesville, Ky., a delegate from the Daviess County Medical Society to the State Association. He called me back because he saw the association, with the profession so loved and so upheld, being placed upon the plain of politics by a self-nominated candidate for the presidency, openly soliciting votes in direct violation of both the written and unwritten law of the association. Other loyal doctors returned as I did and saved the association by electing a doctor that the office sought instead of one who in violation of the association's law sought the office.

I was asked what I thought of Mr. Herrington's bill changing the law permitting the Governor to appoint any doctor upon the Board of Health and changing the headquarters to Frankfort. I answered that in my opinion that law would be disastrous because under the present plan the Governor could only appoint from doctors already selected by the association of the several schools of medicine which would insure a competent doctor upon the Board; because doctors can better judge a physician's ability to serve upon the Board just as a lawyer can best judge a lawyer's ability to serve upon the supreme bench. I also stated that in my opinion it would be unfortunate to remove the headquarters of a scientific department to the politically permeated atmosphere of Frankfort.

STATEMENT OF DR. L. S. McMURTRY.

Dr. L. S. McMurry, of Louisville, being duly sworn by the Chairman of the Committee, was asked to state to the Committee Dr. McCormack's relations to the medical profession. Before replying to the question, Dr. McMurry asked Chairman Schoberth if he desired him to answer the question briefly or in full, to which the Chairman told him to answer it in a way that would give the Committee the information fully but to be as brief as possible.

Dr. McMurry said: The relation which Dr. J. N. McCormack sustains to the medical profession involves, of course, the respective positions which he holds. As Secretary of the State Board of Health of Kentucky he is the executive officer of that Board and consequently the health officer of the State. The various functions of this Board, relating to protection of the public health, stamping out epidemic diseases, inspecting possible unsanitary conditions and recommending legislation, regulating common carriers and abating nuisances, and preventing the dissemination of epidemic diseases among people and animals is known to all the people who take an interest in these important matters.

But the most important work in which he has engaged is as an official of the American Medical Association. This is the largest organized body of physicians in the world. The organization is national in scope, but has its component organizations in every state of the union and in the counties of every state. This organization owns and publishes the best weekly medical journal in the world, recognized everywhere as presenting the highest standard of medicine, both practical and scientific. One of the chief purposes of the American Medical Association is to improve the scientific attainments and educational standing of the country and village practitioner of medicine. While the city physician has access to libraries, laboratories, and hospital instruction, the country physician is deprived by his isolation of these facilities for improving his knowledge. During the past two decades the science and practice of medicine has been completely revolutionized; it has been necessary for the medical profession to re-educate itself. The American Medical Association has undertaken to do this great work, and Dr. McCormack was placed at the head of this great undertaking. To visit the practicing physicians in every state of the union, to organize them into county medical societies, and interest them in the study of modern science and modern methods in his special field of labor. There is nothing in the American Medical Association or in its work that relates directly to the commercial

side of medicine. Its work is to stimulate scientific investigation and diffuse knowledge, and thereby to elevate the standard of proficiency of the profession and give the people the advantage of modern scientific discovery.

Another and incidental part of Dr. McCormack's work is to deliver lectures to the public, the non-medical public, to explain the laws of health and how to prevent disease, with correct teaching as to preservation of health and the prolonging of life. It has also been an important part of his official duties to address the legislatures, upon invitation, in the various states, and acquaint them with the great importance to the people of proper health legislation, so as to prevent diseases and protect the people from imposition and adulterated foods and drugs.

To discharge these difficult duties has required a man of exceptional qualifications. His footprints are on every hillside and valley from Canada to the Gulf and from ocean to ocean. He has addressed academies of medicine, composed of the most distinguished physicians and scientific investigators in the various cities of the country, and also assemblages of country doctors in the court-house of almost every county in the various states. This work has required unusual tact, unflinching energy, exceptional ability, and enormous sacrifice of personal comfort and convenience. He has practically been an exile from his home, and no other man with whom I am acquainted, possessing equal abilities, would for the same salary have done the work. He is personally acquainted with more physicians than any other man in the United States, and has done a work in the medical profession the beneficent results of which are incalculable. And while carrying on this great national work, he has always taken the time to keep in touch with his work here in Kentucky, which he has nurtured and developed through thirty years of incessant service.

STATEMENT OF DR. LILLIAN H. SOUTH.

I never appeared as a witness before a distinguished body like this, and, being a laboratory worker and a woman, I ask you to permit me to present what I have to say of my work in writing and will then be glad to answer any questions about which you wish other information.

I am a native of and was educated in the graded schools of Bowling Green, and later received my B. A. degree from Potter College, in 1896. I graduated from the Nurses Training School of the Central Hospital at Patterson, New Jersey, three years later, but shortly after began the study of medicine and graduated from the Woman's Medical Col-

lege at Philadelphia in 1903, and then spent two years as interne in the hospitals there, giving special attention and study to bacteriology, for which I had a strong liking.

I began the practice of medicine at Bowling Green with my father but after he left there formed a partnership with Dr. A. T. McCormack and opened in my old home, after building a large addition to it, a hospital quasi-public, to which every physician in my county may bring his patients on the same terms. This hospital is incorporated as a charitable institution, and under its charter every cent of its income must be and has been spent for maintenance and improvement. This is the only hospital in Warren county and is used, when necessary, both by the county and city, and we have been able in it to care for any sick boys and girls among the hundreds attending the many schools in Bowling Green, who live in boarding houses and away from the care of their families and need good care and nursing when sick. Of course these sick people are attended by their own physicians.

The first appropriation bill for the State Board of Health was passed four years ago. I was promised the position of State Bacteriologist by every member except Dr. McCormack who objected on account of my partnership with his son. This bill was vetoed by Governor Willson but when funds were supplied by the next legislature I was elected to the position unanimously, but before entering upon the discharge of my duties took a course in this special State work in the Laboratory of the State Board of Health of Virginia, in the laboratories at Philadelphia and for a short time at the Hygienic Laboratory of the U. S. Public Health and Marine Hospital Service at Washington.

We have a very strong medical and health organization and before my laboratory was equipped I was in touch with the health boards and profession in every section. Depots for the distribution of mailing cases and other supplies, for collecting and sending in specimens were opened in every county, with the result that during the first year I examined 3,259 specimens giving aid in the diagnosis of that many cases of sickness. In diphtheria and certain other diseases life often depends on the promptness with which this can be done, and to facilitate examinations of this kind, in addition to the laboratory in connection with the Board, I opened a small one in the hospital adjoining my room and its only cost to the State was for equipment and gas, free of rent, and have a messenger meet every mail, day and night and am thus able to start the cultures received at any hour. I accepted this position at a small salary and with the understanding that it would not seri-

ously interfere with my practice, but the work grew so rapidly that it soon occupied my entire time and since I have discovered hookworm in twenty-five counties four assistants have been given me and with the increase in my salary I practically retired from other practice, than giving anesthetics, to give my entire time to these duties.

The Board also requires me to keep on hand in a large refrigerator fresh supplies of antitoxine for diphtheria, secured by contract, upon competitive bids, which is supplied to fiscal courts and health boards at the special price we pay for it. Not one cent of this money is handled by us, but accounts are sent direct from the firm which makes the antitoxine to the fiscal court or other purchaser. Since July 15th last, when this supply became available, I sent 1,131 packages of antitoxine to be used in the treatment of about 600 children, only a few of them dying, whereas, under the old regime 40 per cent, or about 200 would have died. To say nothing of the saving of life, these 1,131 packages actually cost the counties \$1,296, while at the regular price at which it is being sold everywhere the cost would have been \$5,151, a saving of \$3,954 for five months. During the present week the laboratory sent a large number of packages of antitoxine to Carlisle county, where an epidemic of diphtheria is now prevailing at a rate which will save more to that county than its part of the entire appropriation of the Board for a year.

Again, through the Hygienic Laboratory at Washington, I obtained the serum free of cost and gave the preventive treatment of eight cases of hydrophobia. The serum for each case to physicians costs \$75.00 and the ordinary and proper charge for treatment is at least \$150.00, as the treatment extends over 21 days. Everything is free to the people of Kentucky, in my laboratory, and in these eight cases alone the saving to the distressed families or counties may be roughly put at \$2,000.00. The 3,259 specimens I examined during the year at the low estimate of \$3.00 each would have cost somebody \$9,777. As the total cost of the laboratory for the year, including salaries and equipment, was only \$4,078, it looks to have been a good investment. I naturally feel proud of this record and, am glad of the opportunity to tell you about it, and thank your constituents and to give you any information which will enable you to give the people of your respective counties full knowledge as to the great work the General Assembly of Kentucky is permitting the State and Board of Health to do toward saving the health and lives of its people.

STATEMENT OF DR. A. T. McCORMACK

What are the charges that bring a subordinate health official from his desk and work before this honorable tribunal? The gentleman who has heralded himself through the press as the kindly but vigorous prosecutor seems to have unwittingly rediscovered Abdullam's Cave that he has been able to arouse so many groundless suspicions, and it appears that the officers of this Board and of the State Medical Association must disprove and dispel all the accumulated misinformation and complaint garnered these thirty years. Whether these come from the less than half a dozen unappreciated geniuses in my own profession who have felt that I had in some degree retarded their aspirations for office, or from the vain letters of foolish inquiry addressed at random to my fellow citizens of Warren county asking for information along whatever line would discredit either my father or myself, or from the intimations I have had from one source or another as to the scope of the investigation laid out by the Gentlemen himself, I gather that I am summoned by him as his witness before this Committee of distinguished lawyers to support his contentions, about as follows:

"That the Kentucky State Medical Association is a political machine dominated and controlled by one man for selfish purposes."

The Association was formed in this city fifty-seven years ago, by Gross, Flint, Yandell and men of that type and its activities are guided by its charter, the second section of which follows:

"The purpose of this Association shall be to federate and bring into one compact organization the entire medical profession of Kentucky, and to unite with similar Associations, to form the American Medical Association, with a view to the extension of medical knowledge, and to the advancement of medical science, to the elevation of medical education, and to the enactment and enforcement of just medical laws; to the promotion of friendly intercourse amongst physicians, and to the guarding and fostering of their material interests; and to the enlightenment and direction of public opinion in regard to the great problems of state medicine, so that the profession shall become more capable and more honorable within itself, and more useful to the public in the prevention and cure of disease, and in prolonging and adding comfort to life."

Permit me to present you with a copy of the JOURNAL which was sent to each member of each county society before the last annual meeting. Please turn first to page 734 and note the apportionment in the House of Dele-

gates. Our system of government is modeled after our State form of government and this House of Delegates is an elected body just as you are. I hand you herewith a roll-call for the last session. Look over this list and you will find the names of 103 men, more than 70 of whom were present, and you will find that they compare favorably with any body of men which has assembled in this or any other State in recent years.

In our constitution there are two unique features. It is provided that no delegate shall be eligible to any office except Councilor, and that any member known to have directly or indirectly solicited votes for or sought any office within the gift of the Association shall be ineligible for any office for two years. Article ten provides for a referendum vote to the general membership and this includes the initiative. Such a vote has been taken twice and practically the entire membership voted.

Section three of Article eleven of the By-laws of every county society in Kentucky provides that "agreements and schedules of fees shall not be made by the society" and gives the lie to the frequent assertion of a "medical trust." On pages 757 to 766 inclusive you will find my annual report from which I desire to read one extract:

"The first and greatest cause for congratulation has been the democratization of the organization. As we older members of the profession look backward to the old order of things where from forty to a hundred of the best of doctors gathered together and passed the few days of the annual session in pleasant scientific work, passed a few resolutions which could have little even moral effect unless the newspapers kindly published them, and adjourned. After a few months those who were present would receive a monument to the session in the shape of a volume of transactions. Thirty-six hundred of the four thousand doctors in Kentucky never knew that there was a Kentucky State Medical Society, and a large proportion of them never realized that they were members of a profession and owed it obligations as distinguished from their own individual work.

"Since the reorganization how changed is all this. Many of our county societies have a larger attendance at their monthly meetings than the entire State used to have! Campbell-Kenton, Fayette, Harrison, Bell, Clark, Adair, Henderson, Warren, McCracken, Logan and many others have accomplished more for the welfare of their members and the people they serve in the past two years than the whole profession of the State was formerly able to do. Every physician in Kentucky worthy of the name is assisting in this great work and is represented by a duly elected representative at our annual gather-

ing. Every county society is advised sufficiently in advance of each annual session of every detail of our general work to select and instruct its delegates that every individual in the entire membership may, if he desires, make his influence felt in every item which goes to make up a harmonious whole."

I will ask you to glance at our November issue containing the minutes of our sessions. Each of our constituents may there read every committee report, every motion and every word used in extemporaneous discussion, and so be advised as to every action of the House of Delegates and of his own delegate as to know whether or not to re-elect him. There are 3,331 physicians in Kentucky of which 2,431, graduates from every school or system of practice, are members of our Association. That they are, or can be controlled by any man or set of men is as bare a libel as that a lobby or set of lobbyists can control this Committee, the House of Representatives or the Senate of Kentucky.

Gentlemen: You have seen our JOURNAL. It reaches every doctor in Kentucky. I am requested by our Council to ask that you instruct your stenographer that every question and answer asked here be faithfully transcribed and that we be given a copy. Without expense to the public treasury we will print an edition which will reach every nook and corner of the Grand Old Commonwealth, and we will ask that if there be any man, woman or child who has aught to add to this investigation that will show any fault in the administration of our health or medical laws or any by which more lives can be saved, that he speak now. We will get this edition out at once, Mr. Chairman, so that you may hear what you can while the General Assembly is yet in session. If there were anything wrong, Mr. Chairman, the Association, of which I am proud to be the spokesman, would have known it and would have demanded of you that it be righted. All we now ask is that you expose the motives of the few small men who instigated this investigation, that you know everything worth knowing about our work and our relations with our profession and the people, and that you then make such a report as will continue for us the confidence and moral support of the General Assembly.

And it is also charged that I have worked with and been loyal to my own father, in that when charges that I knew were without foundation were unjustly brought against him I called upon his friends and mine to assist in confuting and disproving them. To this, Mr. Chairman, I must plead guilty, and, in extenuation of the offense, if it be one, it is proper that the Committee be told things somewhat personal and yet which may well

find a place amongst the archives of Kentucky.

My father was one of sixteen children. His education was obtained from self-imposed studies by candlelight after doing his hard share of farm work. He earned the money, which, carefully hoarded, put him through his medical college, from which he graduated with first honor. Amongst my earliest recollections of him was the trying time of the yellow fever epidemic in '78 and '79, when he came home exhausted night after night to snatch a few hours sleep from work with the sick and dying, seconded only by a few heroic Sisters of Charity. This brought him to the attention of the Governor, then forming the State Board of Health, recently authorized by the General Assembly, and in 1883 he became its Secretary and executive officer. I was then eleven years old, and, under the proud but unsalaried title of clerk was initiated into the then but developing science of preventive medicine. From that day to this I have shared his every thought, public or private. Day after day and night after night my mother and I pecked away with tired fingers at the typewriter or wrapped and unwrapped diplomas before our own fireside, because the meagre income of the Board was too small to pay for an expert stenographer or even for light or fuel, when human suffering and human lives could be saved by our self-denial. Until the past year, Gentlemen, I have hardly know what home life meant. Every member of our family, and our servants, have helped to do work, otherwise left undone, and without expense to Kentucky. After this investigation is over it will be easy for the people of Kentucky to know that that man never harbored a selfish or ignoble thought. About his very traducers at this time I have heard him wonder if they could fill any useful place, however slight, in the life-saving work he was planning for his people. An exile from a home, where he is adored, and a circle of true friendship in Bowling Green, it has been his lot to wander over the State where death and pestilence have gone. His life has been an open book and every page denies the paltry insinuations that have been brought before you. He needs no defense from me nor anyone, but I would be false to every honest instinct, knowing the facts as I do, if I had not rallied to his defense and to that of the work to which he is devoting his life all that force of public opinion which his honorable career for thirty years have builded about him. As he descends into the evening of life, Mr. Chairman, defended by the conscientiousness of a life's labor worth the doing, supported by our own profession with such practical unanimity that it is small wonder that little men think all

this is an artificial machine, every Kentuckian will realize that he has builded for himself a greater monument than can be built with hands, and as time passes a tribute will be paid him and his work in the patter of little feet and the prattle of little voices that without him had been silenced, for his life has been spent to save the health and lives, and the resulting happiness and vigor of the children and the men and women of Kentucky.

STATEMENT OF DR. W. H. WATHEN.

I have known Dr. J. N. McCormack since he began his work as Secretary of the State Board of Health of Kentucky, and there are but few men in the State more familiar with the history of this work than I. Since 1893, excepting a few years, I have been Referee of the State Board for the County of Jefferson and the City of Louisville. This brought me in close relation with the Board and with the work of Dr. McCormack. As Referee, for many years I organized the County Board of Health, and this was then independent of the County Judge or the Fiscal Court, all the appointments being made by the State Board of Health upon my recommendation. I do not remember that during these years Dr. McCormack ever suggested the name of anyone for an appointment upon the Board, leaving it entirely with me. The recommendation of men for these appointments had no political significance, the selection being solely influenced by the fitness of the individual for the work that was required. Republicans and Democrats were alike appointed. The President of the Board for several years was the late distinguished Dr. Geo. W. Griffiths, a life-long Republican. This Board never tried to exercise any political influence, nor was the Board influenced in its appointments and its work by the suggestions of Dr. McCormack any further than was necessary to make the work efficient and conform it to the health laws that govern our State. As far as I know the same freedom of political bias was exercised in the County Boards of Health throughout the State. My intimate knowledge of the work that Dr. McCormack has done as Secretary of the State Board of Health in the interest of the betterment of the sanitary conditions in Kentucky, compels me to believe that he has performed the duties of his office efficiently and honestly, and he has probably done more good work, considering the small appropriation of our State for health purposes, than any other state secretary in this country. During all these years the accusations against him have usually been made by personal or professional enemies, and often for selfish purposes. I do not believe there is a man in the medical pro-

fession in Kentucky who could, all in all, have done so much good work as Dr. McCormack.

I have also kept in line with Dr. J. N. McCormack in his work in connection with the State Medical Association. He has done more to uplift the Association and to give it standing with the profession of the country than any other physician in Kentucky. His record in relation to the State Medical Association is absolutely clean, and his work has been mainly altruistic. He, like myself, has been honored by his election to the presidency of the association many years ago, and I am sure that neither of us employed political methods for this office. When his son, Dr. A. T. McCormack, was elected secretary of the Association and editor of its JOURNAL several years ago, at the meeting of the Association in Owensboro, I personally know that the father advised against his election, believing that it would be a sacrifice to accept the office. My purpose in urging the election of Dr. A. T. McCormack was to bring the State Board of Health in close relation to the State Medical Association, so that both might work harmoniously in the interest of the medical profession and the health of the people of Kentucky. The work of the Board by this means could become more efficient and the doctors of the State educated better in what the Board is doing and in what is best to be done to prevent disease and to improve health conditions. The members of the State Medical Association can have no possible interest in purely political questions and their work in the interest of the health department of Kentucky is entirely unselfish, and financially against their own interest. When a member of the County Health Board of Louisville, and in fact its organizer, I certainly felt under no obligation to the State Board of Health or to Dr. McCormack. The office paid me nothing, caused me much annoyance and the expenditure of a considerable amount of money. No one thanked me for the work I did. It was a very disagreeable position and one that no honest man could accept for the purpose of political influence or selfishness. I believe that the members of other county boards of health feel just as I then did, namely, that they are under no obligation to the State Board or to Dr. McCormack because of their appointments. For me to believe otherwise would be to place a low estimate on the personal and professional honor of these men. It would be against the efficiency of the work of the State Board of Health to separate any of its departments, and it is better also, that the Secretary and the editor of the JOURNAL of the Medical Association should be in close proximity to the Health Department. The work of all the

departments of the Board may be correlated, resulting in more efficiency. In reviewing the history of the State Board of Health since its organization up to two years ago, one is astounded at the great amount of good work it has done with so little money—\$5,000 or \$6,000 a year. Then the \$30,000 now appropriated is relatively inadequate for good work, compared with the liberal appropriation for the same work in our better states. It must be remembered that the work of the State Board of Health in the prevention of disease, in controlling epidemics, and in fact in nearly every duty within the province of the Board, is for the benefit of the people, and the State should show its hearty appreciation of the efforts of the medical profession in matters of this sort. I have also been in close touch with Dr. McCormack in the splendid work he has done in the reorganization of the American Medical Association, which is the largest, most representative and the most efficient medical association in the world. He is more responsible for this reorganization and for the uplifting of the medical profession, and especially the country physician, than any other man. The work of the Association is now known, appreciated and complimented by the medical profession in all parts of the world, and the Journal issued by the Association is the best weekly journal for the general physician that is published in any country. The work in the State Board of Health and the National Association compelled Dr. McCormack to relinquish a lucrative practice, to absent himself much from his home, often subjecting himself to the dangers of contracting contagious diseases. He has resigned his office in the American Medical Association so as to devote his entire time to the duties of the State Board of Health, for which he is paid practically nothing.

STATEMENT OF DR. W. ED. GRANT.

This statement is made by me for the Committee appointed by the Legislature of Kentucky to inquire into the management of the State Board of Health.

I am Dean of the Medical Department of the University of Louisville, and in this capacity have charge of the education of about four hundred young men who have been admitted into that institution by the examiner of the State Board of Health. I am Health Officer of the City of Louisville, and through the courtesy of the State Board of Health have been attending their meetings. I am also a member of the County and State Medical Society and the American Medical Association and attend these meetings where I frequently meet Dr. J. N. McCormack. I wish to say that at all times I have found him most efficient in promoting the work of every so-

ciety he attended, but his efforts were always lent to the forwarding of interests that had for their purpose the rapid and efficient accomplishment of the scientific purposes of the society, looking at all times to the improvement of public health, public morals and higher education. I have found him to be perfectly reliable and the soul of honor. I have never had any reason to suspect him of scheming to mislead anyone by the methods of a politician, for his efforts have always pointed to deeds that were of the noblest character. I have always found him untiring and ever watchful of every movement that promised to help others to carry out plans that would save life and promote the health of the whole community. Through suggestions of his, the State Board of Health has assisted the health authorities of this city in accomplishing much creditable work. Such men need the support and commendation of all good citizens, and I utterly deprecate every effort to hinder his usefulness.

SUPPLEMENTARY STATEMENT BY DR. J. N. McCORMACK.

This was not included in my first statement because the newspapers, my only source of information, led my associates and myself to believe that the investigation related solely to the expenditure of the appropriation made for the use of the board by the State.

The first medical practice act, providing for a board of examiners for each congressional district for nongraduates, was passed in 1874, a fee of \$20 being charged by these boards to meet the expense of the examination.

"The State Board of Health took general supervision of this work when it came into existence four years later, but so many bogus and correspondence school diplomas were registered and local and itinerant quacks had such a sway in the State that the law was amended in 1888 so as to require all diplomas and schools to be certified by the State Board of Health, or one of the three state medical associations. Each of these associations voluntarily and in writing requested the board to certify all diplomas under the law, and the duty of doing it was assigned to me.

A fee of \$10 for each certificate was fixed by the law, but in order to make compliance with it popular and easy, I at once announced that it would be done without charge. In about four years most of the physicians had complied with the law, but in operation

it proved so defective that in 1893 the present law was enacted requiring a certificate from the board, registered in the county of residence, as authority to practice, and all the work had to be done over again.

STACKS OF DIPLOMAS.

Month after month, under both of these laws, my residence was filled with stack of diplomas often running into the hundreds, to be unpacked, compared, certified, packed and reshipped. For several months during the stress of it, under both laws, I gave up my practice to others and devoted the entire time of myself and family to it.

This law required a fee of \$2 for each certificate to meet the clerical and other expenses of putting it in operation, but the fee was not required in several counties, as to physicians long in practice, and of those in all counties who were active in securing compliance with the law.

In spite of all this, there was much misunderstanding about and opposition to the law. In order to overcome this I visited many sections to meet members of the profession in person, and the correspondence was an enormous one. In about four years the bulk of the profession was registered and soon there was not an itinerant or advertising doctor in Kentucky, the only State in which such results have ever been accomplished. We have done all the clerical work ourselves; the expense for lawyers, detectives, printing, postage and express during all three years had been considerable, and after this had been met in 1896, of the total amount of \$4,977 collected to that date, a fund of \$2,400 was left, and, in partial compensation for our services, this was turned over to me, as were the fees for future registrations, after defraying the expenses incident to the continued operations and enforcement of the law.

REGISTRATION FEE INCREASED.

The amendment of 1904 increased the fee to \$10, but it was found that there were still many applicants who were entitled to and did register under the old law. It was soon found that the increased fee provided more compensation than the duties entitled me to, and without formal action of the board, the fund was permitted to accumulate. This amendment provided that graduates from schools outside of Kentucky should be examined from its passage and that all applicants should be examined after 1907. This for the first time imposed laborious du-

ties upon the other members of the board in the examinations proper, and in the grading of papers, and as the income under this law was never sufficient to pay the full compensation to which they were entitled under its provisions, and as the board always felt a freedom in using this fund which did not apply to that appropriated by the State, and on account of the increased duties it was decided in May, 1906, that the accumulated fund and future fees, after paying all expenses, should be divided in the ratio of one-tenth for each member, and three-tenths for the secretary.

In the intervening six years, under this arrangement, as will be shown by the accompanying financial statement and vouchers, each member has received \$450 in addition to expenses, and I have received \$1,350, and, as nearly as can be calculated, distributed over the twenty-nine years I have had supervision of the law, I have received annually an average of about \$250, and a total of about \$7,250.

VOUCHERS SINCE 1906.

In this connection, it may be proper for me to say that since your last adjournment I have gone over the accounts of all the funds and find that the payments to me and my son, including the pittance to my wife, under both laws, outside of traveling expenses, amounted to \$2,000 annually, for the twenty-nine years, aggregating \$58,000, out of a total revenue from all sources of \$167,000, for doing practically all the work, except the examinations in recent years.

This statement and the itemized accounts and vouchers since 1906 are submitted in accordance with your instructions as to this fund at your last sitting.

STATEMENT OF DR. W. W. RICHMOND.

I have been intimately associated with Dr. J. N. McCormack in the Kentucky State Medical Society for nearly forty years. During all that time I have never heard him say nor known him to do anything that would lead anyone to conclude that he had the slightest tendency to dominate or control the Society. To my knowledge he has always opposed a policy of that kind, and I have often heard him so express himself. There was a time in the early history of the organization when the Society was largely controlled by certain individuals whose aim was personal benefit rather than the interest of the Society. This pernicious system continued until it was recognized by the more thoughtful that the usefulness of the organization was waning and the membership of the Society was falling off, being composed of less than one-tenth of the doctors in the State at that time. On

that account, a move was made headed by Dr. McCormack to reorganize the Society and in that way get rid of the offending cause, increase the membership, and extend the usefulness of the Society to every county in the State.

A new constitution was written by Dr. McCormack and adopted by the Society. The Society is working under that constitution at the present time. It provides that the State Society shall be composed of the County Societies in the State, each County Society constituting a component part of the State Society. It also provides that the State Society shall be governed and controlled by a house of delegates, composed of a delegate from each County Society in the State. The House of Delegates, among other things, elects all the officers, and no delegate can hold office except that of counsellor.

Therefore it would seem as impossible for any one to dominate or control the Kentucky State Medical Society as it would for a member of the State Legislature to dominate and control that body, and even more impossible for Dr. McCormack, carrying out his views long before expressed, embodied a clause in the constitution which provides that any member soliciting office in the Society shall be disqualified for holding office for a period of two years, a safeguard against the possibility of any one dominating or controlling the Society.

Dr. McCormack has given more thought and study to the subject of Medical Organization and the maintenance of the same than any doctor in the United States. He was instrumental directly in the organization of every County Society in Kentucky, and the results have been far reaching: not however, farther than he anticipated, for he not only succeeded in the organization of good working County Societies, and bring the doctors together in a bond of professional fellowship, a thing that had never been done before, but he inculcated in them the principles of preventive medicine so that through them he is doing more to prevent sickness and to keep people from dying than all the other forces in the State put together. Instead of dominating, Dr. McCormack has done more to pacify and bring doctors in closer relation to each other, to improve medical ethics, to raise the standard of medical education, and to encourage doctors to study and better prepare themselves to prevent sickness and treat diseases, than any other doctor in the United States. It has been charged that Dr. McCormack has been overpaid for his work when, as a matter of fact, it has been done at a serious sacrifice.

His work has been largely altruistic, full of the spirit of human kindness, and he has

always felt a deep sense of what he conceived to be the duties of the medical profession to suffering children, women and men. There are so few men of his class in the world that it is hard for some people to believe this statement, but to those who have lived close to Dr. McCormack, and who know him best, the statement is no surprise and readily believed. Notwithstanding the adverse criticism of a few people who have had aspiration without ability, and who have failed to realize their fondest hopes in the present organization and who know but little of the work that Dr. McCormack has done and is doing; and who have put themselves to no trouble to find out, it is gratifying to know that he has the love and confidence of all the people and more than four-fifths of the doctors in Kentucky.

STATEMENT OF DR. JNO. G. SOUTH,
PRESIDENT STATE BOARD OF
HEALTH.

To the Committee on Kentucky Statutes:

GENTLEMEN:—

Believing that there has been a deliberate effort on the part of some persons to create an impression upon this Committee and upon other members of the Legislature that I am urging this investigation, and that I desire a change in our present medical law, and that I am personally opposed to Dr. J. N. McCormack, I desire to file this statement.

I have known and been associated with Dr. J. N. McCormack in health work in Kentucky for the last thirteen years. I know his character as a man to be of the highest type, his reputation as a physician and health officer to be of the very highest. He stands second to no man in the world in health work. Kindly allow me enough of your valuable time to tell you something of the service he has rendered here in Franklin county. This county was visited by a severe small-pox epidemic in the summer and fall of 1900. This was the first small-pox epidemic in Kentucky within the memory of the younger generations, therefore, the people of this county and state were panic stricken. The people, through history, knew of the terrible ravages of the disease and all of its loathsomeness. We appealed to Dr. J. N. McCormack for help. Within twelve hours he was here in person. He at once put in quarantine all small-pox cases that could be found and all who had been exposed to the disease. He requested the Mayor to call a meeting of the city council, and the County Judge to convene the Fiscal Court. Arrangement was immediately made by these bodies, with the assistance and advice of Dr. McCormack, for the quarantining, treating, clothing and feeding of these people. I was the physi-

cian selected to care for those afflicted. It was now that I began to know and appreciate Dr. McCormack, the man, and Dr. McCormack, the health officer. He was at all times firm in the enforcement of his duties, but withal, gentle and kind to all those afflicted. His first advice and instructions to me were to protect the public from the disease at any cost, but that I should also save the county and city every expense possible. This county and city did not at that time possess an eruptive hospital. He said this was to be regretted, but that we would at once establish camps for both those who were afflicted with the disease and for those who had been exposed to it, but had not yet developed it. This being decided upon, he personally vaccinated me and all others that were to assist in transporting the patients to the camp, also all those who were to be employed at the camp. He personally arranged the details of the camp, organized it, and with the assistance of James A. Scott, James H. Graham, L. F. Johnson and other public spirited citizens, removed the first patients to the camp. This was done in the dead of night. People near the camp site and along the road leading to it were thrown into such a panic that they tried to prevent the establishment of the camp near them and actually fired upon us. Dr. McCormack stuck to his work notwithstanding the fact that his life was in danger from bullets and disease. All this without one cent pay other than his meager salary as chief health officer of Kentucky. There were hundreds of people afflicted with this epidemic but by his wonderful executive ability, energy and skill the last patient was dismissed as cured and safe to the public just sixty-three days after the first case had been reported to him. Within a very short time he had practically every person in this county and city vaccinated. This remarkable work will be but one of the many monuments he has built for himself throughout Kentucky. Having been associated with him in health work practically all the time since that terrible time, I want to say that his work has been of the highest type and I have never known him to fail to perform a duty. Kentucky could ill afford to lose such a man in this great work. Need I say more of the man? I have heard much of the lack of harmony in the work of the State Board of Health. All strong minded men have opinions. The people are benefitted and the men are benefitted by the free expression and exchange of opinions. Dr. McCormack and all members of the Board have freely discussed matters that have come before it, and have sometimes differed as to what was best. I am glad to say, however, that in practically every question that has come before the Board the vote (after these discussions) has been

unanimous. The minutes of the meetings bear me out in this. As to our medical and health laws, my belief is that they are all-right, insofar as public sentiment and our limited means will enable us to enforce them. This will be accomplished by increased appropriations and a campaign of education in sanitary and health conditions. "We want a league, offensive and defensive, with every well wisher of Kentucky and her people."

The present manner of selecting members and their appointment by the Governor with the consent of the Senate is ideal. It has been charged that Dr. McCormack has a machine in this law that keeps him in office as secretary to the Board of Health. He has held the same office for thirty-three years continuously. I ask: "What kind of a machine kept him in this office for a quarter of a century prior to the enactment of this law?" I believe the man was built for the office and not the office for the man. As to the suggestion of removal of the Board of Health offices to Frankfort. I am and have always been deeply interested in Frankfort and her people and their welfare. It is not at all practical to remove these offices here at this time, at least. We can not house them. We would first be compelled to have an appropriation of not less than fifty thousand dollars to erect buildings for the offices and laboratories. May I repeat that I ask to file this because of the false report that I do not endorse Dr. McCormack or his work nor the present medical laws of our State. As President of the Kentucky State Board of Health, I deem it not only a privilege but a duty to endorse Dr. McCormack and his work, and also the medical and health laws that he has so faithfully executed.

I most respectfully ask for the welfare of our people, that this Honorable Committee commend Dr. McCormack, his work, and the present medical law to the Legislature and the people of Kentucky, and that Mr. Herington's bill be reported adversely.

Most respectfully submitted,

JOHN G. SOUTH.

LETTER FROM DR. M. K. ALLEN.

Louisville, Ky., February 15, 1912.

Hon. H. B. Schoberth, Chairman,

Frankfort, Ky.

To the Committee on Kentucky Statutes of the House of Representatives, who have under consideration the bills affecting the State Board of Health of Kentucky:—
Gentlemen:

Having been engaged in Public Health work for the past fifteen years, I feel that I know something of the importance and value

of public health work to the people, whether administered by the National Government, individual States or municipalities.

As Health Officer of the City of Louisville, Ky., for ten consecutive years I was constantly and intimately associated with the doings of the State Board of Health and I feel that it is but just to this body to say that unquestionably they have rendered the people the most valuable service that could be done by any department of our State Government.

For years I have known many of the public health men of this country and I regard Dr. J. N. McCormack the best public health worker in the United States. He is exceptionally intelligent, honest, earnest, industrious and most thoroughly capable from long training. His fearlessness in the fight for pure food and good sanitary conditions has in the many years he has served the people very naturally made enemies for him, as was the case with our great National expert, Dr. Wiley. No man can fearlessly enforce health measures without infringing on the supposed personal and selfish rights of violators of the law.

The people of this Commonwealth can never pay the debt of gratitude they owe the members of the State Board of Health, who have given their very best professional services and time, as against their own interests, in an effort to protect her citizens against disease and death.

It would be a calamity to this State to lose Dr. McCormack as a Health worker either by death or retirement. A competent, faithful and trained health worker is a rarity and it is highly possible that many, many years will pass before the people of this State see and know another McCormack.

If he is willing to continue to make the great sacrifice he has been making for years, let's not fail to utilize him, giving him every possible facility to further this great work.

Very respectfully,

M. K. ALLEN, M. D.

LETTER FROM DR. REYNOLDS.

Louisville, Ky., January 25, 1912.

Dr. Jos. N. McCormack,

Frankfort, Kentucky.

DEAR DR. MCCORMACK:

I am amazed to observe the names of some of the reputable members of the Medical Profession of Madison County, engaged in a political scheme to cripple Kentucky's best asset, the State Board of Health. I was at Frankfort in April, 1878, when the Legislature passed the first Act creating this Board, and well remember the interview or private discussion Dr. Sawyer, Doctor Pinekey

Thompson, you, and I had concerning the extremely limited authority the Act extended to the Board.

I have watched your efforts and the general growth and expanding influence of this noble, and beneficent work, with increasing interest, and I must say you have honored the State of Kentucky beyond my powers of description in the enthusiastic and successful efforts you have made during the past thirty years.

It is an insult to the intelligence and the dignity of the Kentucky State Medical Association to even insinuate that its conduct has been dominated by any man or any set of politicians on earth. I have been a member and a pretty constant attendant at the meetings of the State Medical Association for more than forty years, and feel entitled to express an opinion concerning its work. No political discussion has ever been introduced at one of its meetings. Its character and standing in the intellectual world is as high as that of any similar organization in this or any other country.

If the people of Kentucky cannot trust the State Medical Society to nominate persons for membership in the State Board of Health, I am sure it would be suicidal to permit the politician to name them.

With abiding confidence in the ultimate triumph of truth and justice, I await your complete vindication.

I am, very sincerely yours,

DUDLEY S. REYNOLDS.

LETTER FROM DR. J. H. SAMUEL.

Dr. J. N. McCormack, Secretary,

Bowling Green, Ky.

MY DEAR DOCTOR:

Some unknown has been mailing me "marked copies" of the Courier-Journal.

I am writing simply to say that I firmly believe you never knowingly did a wrong act and that you have ever had the general welfare of the entire profession at heart.

I went—or, rather, was appointed upon the State Board with a specific understanding: the nature of which I once explained to you at the Galt House.

Watching you through not the most friendly eyes—due, of course, to what I had been told—I was driven—most willingly—to admire and respect every professional or official action that you made. I know that you have a hard fight and to many by no means an enviable one. You will come out victor—because you are, as you have always been, in the right and for the right and the best. I may never at any time be of much use; but I want to assure you, that I am with you in sympathy

and will most gladly be with you along the firing line.

I am sincerely, yours, etc.,

J. H. SAMUEL.

Maysville, Ky., February 14, 1912.

DR. McCORMACK'S RESPONSE TO THE RULE.

May it please the committee:—Eight days ago, in compliance with a previous agreed ruling I filed with the Sergeant-at-Arms a full and explicit statement as to the practice act fund from 1888 to January 1, 1912, which I read to you and made complete by itemized accounts and vouchers for the years they were required by the board. Not being certain as to what else Mr. Herrington wanted, I asked the Sergeant-at-Arms to inform him that I would be glad to go over the papers with him, explain any matter about which he was in doubt, and supply any data which was lacking.

Hearing nothing from him and weary over the delay and inconvenience to you and my friends, on two occasions, I went to your Chairman and requested him to arrange for a conference between Mr. Herrington and myself for the purpose indicated, and he also failed to secure it.

The President of the Board, its Counsel and myself were promptly at the place and hour for your meeting, on the 8th instant, and after a long wait there and in an adjacent room, we were informed by the Sergeant-at-Arms that a quorum was unlikely, but that upon the promise of one he would at once notify us. While we were resting upon this assurance 30 feet away, Mr. Herrington went before the committee and procured the order of that date.

Like my old friend and co-laborer Dr. H. W. Wiley, the Apostle of Pure Food and Drugs of the Nation, I have been fearless in my exposure and prosecution of the powerful interests engaged in poisoning the people by adulterated and fraudulent foods, drugs and the practice of quackery. For years they spent hundreds of thousands of dollars annually inundating congress with literature plausibly designed to discredit him and myself and our profession until at last they were dragged into the open, their character recognized until he now holds the confidence of the American people to the extent enjoyed by very few men in history.

On account of my relations to my profession and this movement in the State and in the Nation, these interests would gladly do more now in supplying members with slanderous literature and otherwise to bring reproach upon me than they did Dr. Wiley, now that he has escaped them. Many of these people belong to the criminal classes and have no scruples in accomplishing their nefarious

purpose and from the day this investigation started their paid representatives have threaded the halls of this hotel to the room where the Sergeant-at-Arms was trying to keep my records which will one day become beyond value to the profession and people of Kentucky, from the custody of which I ought never to have parted, and which I now ask you to restore to me, I have found them absent, scattered and I suspect in irresponsible hands, and have trembled for their safety.

Not yet knowing exactly what Mr. Herrington wants, and with no time to go over them, I submit for his and your inspection the original applications, with the fee paid plainly marked on it, for every certificate which has been made since December 18, 1895, when my residence burned, at which time previous ones were destroyed; my bank books from the time account was ordered kept separate, in 1906, with income, expenses and vouchers; the scratcher kept by my stenographer, for her own information, of the fees received in the office since 1908, and which I never had occasion to see until Saturday. These, like my other records and papers are priceless and with the constant duties pressing upon your excellent Sergeant-at-Arms, often keeping him away from his room night and day, they are not safe and I again urge that they be placed in my custody, subject at all times to the inspection of Mr. Herrington and your committee or your accredited representatives, to any or all of whom I will gladly give assistance and explanation at any time.

Gentlemen, I have grown gray in the service of my State, serving it longer, continuously in an official capacity than any other man. Cheerfully, though often misunderstood and condemned temporarily by the thoughtless and ignorant, as is to be expected by one leading any reform, I have given the best years of my life to Kentucky and her people, and have been honored as is true of few men. Without a chance to be heard, you ordered me as though I was a criminal to be here at noon of yesterday under pain of contempt. At least, it was so printed in the newspapers.

Smarting under the injustice of it, but as a law-abiding citizen, I traveled all night in order to be here at the appointed hour, to find no one named in the order here to receive them, and searching with due diligence, was only able to find the chairman before the hour appointed for the house to assemble. I have endeavored in good faith, to comply with every request or order of the committee, or frankly explain why I could not do so. I have in the same good faith answered all questions and am glad and willing to do so further at any time.

ORIGINAL ARTICLES

TREATMENT OF FRACTURES OF THE LONG BONES.

By GUY P. GRIGSBY, Louisville.

I am sure we will all agree that we are not utilizing our talents, nor all of the advantages at our disposal, in the treatment of fractures. Especially is this true of fractures of the long bones. I say, without hesitation, that we are not getting the results we should in view of the appliances, the nearly perfect aseptic technic of our present surgery, and the X-ray, that we have at our command. It would seem that there was a lack of interest and a feeling that the subject of fractures was such an old one that it would take care of itself. The brilliant results in thoracic and abdominal surgery have been achieved because the minds and skill of the majority of surgeons have been centered upon those particular subjects at the cost of more or less neglect to other branches of surgery.

Fractures are not receiving the attention of surgeons nor are our teachers in the medical colleges devoting the time and attention to this subject that it deserves. I am quite sure the older members of the profession recall the thoroughness with which this subject was taught when they were students, offering quite a contrast to the present methods of teaching. Without question, the X-ray is more or less responsible for the change. We who have access to this means of diagnosis resort, perhaps too frequently to its use, and should depend more upon the findings after a careful clinical study of the case. The X-ray has greatly advanced our knowledge of fractures, showing that fractures occur in types, and definite types at that; that fractures formerly thought to be common really occur most infrequently. And so, with this knowledge, it is indeed hard for the present generation of surgeons to consider a fracture except in the light of a skiagraph, nor tolerate anything that partakes of the older methods of diagnosis. I do not wish to decry the X-ray, but to consider its employment only in certain cases. It is often unnecessary, and impossible, to have every fracture skiagraphed, adding at times, quite a burden to those of limited means. In certain obscure and special conditions its employment is a necessity. It will always prove itself an exposé of the bad results of the careless and unskillful surgeon.

After a fracture is reduced and suitable dressing applied, the X-ray may be used simply for the assurance of an accurate and proper coaptation of the fragments. The skiagraph should be taken in two different

*Read before the Muldraugh 11th Medical Society, Elizabethtown, December 1911.

planes, crossing each other at right angles; otherwise, some fractures will be overlooked and cause no little embarrassment to him who places his absolute confidence in the X-ray findings.

I wish to deal with the treatment of fractures of the long bones, especially considering fractures of the neck and shaft of the femur, as bad results often occur under present methods of treating these cases, and since the same general plan of treatment as is advocated for them will be applicable to fractures of the other long bones.

FRACTURE OF NECK OF THE FEMUR.

Whitman and others have shown that this fracture occurs very much oftener under the age of fifty than was formerly thought. The diagnosis of this condition is often puzzling, and perhaps mention of the cardinal symptoms will not be amiss:

1. There is usually a history of a fall or violence.
2. Pain is present and is increased on motion.
3. There is outward rotation of limb.
4. Shortening is present, varying from 1-4 to 2 inches, and is probably the most important symptom, and depends upon the lessening of the angle between the neck and the shaft, which approaches more nearly to a right angle upon impaction of the fragments of their displacement longitudinally.
5. Crepitus may or may not be elicited.
6. Loss of function, patient usually unable to draw up heel toward hip.

With these symptoms, and a skiagraph if it is possible to have one taken, the diagnosis can usually be made, but certainly offers greater difficulty in early adolescence and childhood.

I would again remind you that these are the cases that are neglected, being treated for hip disease, growing pains, rheumatism, etc. It may heal in coxa vara, and the symptoms may result from this deformity, or from progressive deformity as the weight is borne.

These cases and their treatment are divided into two classes; (1) recent fractures; (2) old fractures.

In recent fractures, as soon as the diagnosis is made, the abduction treatment, as devised by Whitman, should be instituted at once. A general anesthetic is given, preferably ether. The patient is placed upon a box, or pillow, about eight inches high, and large enough to support the head, shoulders and trunk; the pelvis rests upon a pelvic support, and the extended limbs should each be held by an assistant. The sound leg is then abducted to the normal limit, which is usually about 45 degrees, and the fractured limb is abducted to a degree to correspond to the sound one. Traction is then applied and the

outward rotation is overcome by lifting up and supporting upper end of femur and, at the same time, rotating the leg inward. Measurements are then taken to see that all shortening has been overcome, and if it is still present a greater amount of traction is applied until the two limbs are of equal length. A plaster spica is then applied, from the toes to the costal margin, during the application of which the assistants should maintain their respective positions and use the utmost care not to disturb the fragment. The spica is worn usually for eight to ten weeks, followed (perhaps) by a short spica for three or four weeks. After removal of the plaster, there is usually a tendency to abduction deformity, and this is overcome by daily stretching of limb.

This treatment is used for the aged as well as the young, and I would condemn the almost universal practice of treating these cases by "Buck's extension" and sand-bags, because of the almost uniform bad results that follow this line of treatment. So long as a patient is able to take an anesthetic for 20 or 30 minutes, this is by far the most rational and satisfactory treatment. Several cases have been reported of good functional cures in very old patients where this treatment has been used. I am sure it is quite needless for me to recount to you the advantages of this treatment; results speak for themselves, and the results from this treatment during the past four or five years have proven conclusively that in this condition it gives the best hope for a functionally active hip.

OLD FRACTURES.

In neglected cases, operation with employment of abduction after the fragments have been put in apposition, is the only treatment. A free incision is made over the great trochanter, and site of fracture is exposed. If there is faulty union, this is broken up and the ends of bone freed of callus. It may be necessary to resect a portion of one fragment before they can be placed in proper apposition, due to contraction of the tissues. If the fragments show a tendency to slip, a long spike, or bone drill is passed through the trochanter, the neck, and well into the head of the femur. In this way the fragments are securely held. The drill, or spike, is easily removed by a small incision in about eight or ten weeks. The wound is closed by catgut, approximating like fissures, and, as far as possible, eliminating dead spaces. Plaster spica is then applied with the limb in abduction. I have assisted Dr. Whitman in eight cases so treated, without infection and with a good functional result in all of them.

Now, as to treatment of fractures of the shaft of the femur, there are two methods:

1. By traction and external splints, or reduction under anesthesia and application of plaster of Paris.

2. The operative, or so-called open method, with or without the employment of internal splints.

The first method is familiar to you all, and you have experienced the failures and successes attending the method of treatment; so I will devote no time to their discussion but will deal more intimately with the operative treatment.

Lane, of London, Huntington, of San Francisco, and lately Martin, of Philadelphia, are the most pronounced advocates of this method. R. H. Harte has aptly stated that the profession is divided into three groups regarding the open treatment of fractures: (1) the ultra-conservatives, who rarely, if ever, operate; (2) the radicals, who operate upon nearly all fractures, and (3) the conservatives, those who operate upon properly selected cases, after it is definitely proved that other methods of treatment are not expedient, that reduction is impossible, or that the fragments cannot be retained in position after reduction.

From the first, or ultra-conservative, we would have less mortality and distinctly the most bad results; from the radicals we should have the greatest mortality; from the conservatives we should get the best results consistent with a low mortality.

Theoretically, the open method is the one of choice, but in the light of results from this method in the hands of the best surgeons, its general employment in all cases of fracture cannot, at the present time, be advocated. Practically these points must be considered: That infection may occur, and that occasionally death may ensue from this infection. Infection is favored because the simple fracture is converted into a compound one, and by trauma of the soft parts coincident with the reduction of the fragments. When plates or other extraneous substances are used for splinting the bone, they interfere with the nutrition of the bone and may cause necrosis and caries. On the other hand, considering a fracture as a wound, the sooner and more accurately the surfaces are brought together and retained in position, the less will be the swelling and the more perfect the healing. If, with the open method, primary healing occurs, the disability is much shortened, especially in the lower extremity, and this is of especial importance to the wage-earner. Non-union is preventable, so far as the interposition of tissues between the fragments is concerned. The anatomic result is perfect, in contrast to the noticeable deformities resulting from other methods. Perfect functional results is attained, and even if infec-

tion occurs and the plates must be removed, the bone is usually firmly enough united to give a good result.

Now, as a conservative, what cases should be treated by operation?

1. It is indicated for immediate and accurate reduction of misplaced fragments of long bones, where it is impossible to correct the deformity by other methods.

2. Where portions of the soft parts intervene between the fragments.

3. In fractures involving the joints, because it allows of much earlier use of passive motion, so essential to this class of cases.

4. In recent cases in which the fragments cannot be reduced, or cannot be held in place, after a fair trial, or in cases where there is a disturbance of circulation after reduction of fragments.

5. In all old cases with non-union, or vicious union.

6. Advised to those whose occupation requires much standing and moving, necessitating perfect and firm union, or else their earning capacity will be reduced by the discomfort produced by the strain on the muscles and joints.

OPERATIVE TECHNIQUE.

The following instruments are essential to success in this mode of treatment:

A bone forceps as devised by Lane.

A Lambotte embracing clamp to hold fragments and plates while plate is being secured by screws.

A screw-driver and screw-holder combined. Several bone drills of various sizes.

The following principles must be rigidly adhered to: The use of rubber gloves, immediately changed if punctured—the same precautions for perfect asepsis as are required for joint surgery; *the hands should not touch the wound.*

In the way of preparation, I would advise thorough cleansing with soap several hours before operation, followed by sterile dressing, and the application of iodine at the time of operation. Over site of fracture the skin should be scratched with a pin before operation; this will save both hesitation and manipulation at the time of operation in endeavoring to locate the fracture.

BONE SUTURE.

Many methods have been advanced and used for uniting the ends of the bone-wire, staples, catgut, inter-medullary splints both of metal and ivory, and bone plates. Bone plates and occasionally the use of silver or bronze wire will meet all requirements. An experience with bone plates will convince one that their employment is based upon the right principle. The plates are usually made from spring tool steel, from 1-32 to 1-16 of an inch in thickness, and should have two or more

screw-holes countersunk in either end, but no nearer than 1-4 inch to the end of fragment, or else the screw will tear out. The screws should be of various lengths and sizes. A No. 6 flat-headed machine screw will usually be suitable for a fracture of the femur. Screws should penetrate only one side of the bone and should not enter the canal.

A free incision is made over the site of fracture, the muscles separated and the fracture exposed. It is better to clean out all blood clots. In case of disturbed circulation, look for and relieve the cause; it is usually due to pressure on the main artery, or injury to it. In recent fractures little difficulty will be experienced in reducing the fragments; the longer after the injury, the harder will be the placing in apposition of the fragments, due to the shortening of the tissues. By the use of instruments, and traction, made either by assistants or by weight and pulley, the fragments are reduced. If weight and pulley are used, considerable weight may have to be employed, usually 100 to 150 pounds. A wait of five or ten minutes produces enough stretching of the contracted tissues, which should be stretched sufficiently to allow no strain to be put upon the plates. Endeavor to so place the fragments that there will be no tendency to slip. Occasionally, the fracture may be impacted, or fit so accurately as to require no bone plate or wire to hold it in place. If not, select proper plate, put on embracing clamp to hold plate and fragments, drill holes with a drill a little smaller than screws, and fix plate with screws. Plates may be placed over the periosteum, as results seem equally as good as when they are placed directly to the bone. Close wound with catgut, eliminating as much dead space as possible. A small drain of rubber tissue may be placed in either angle of the wound, but is not essential. Serum will be discharged freely for the first twenty-four hours. Dressing is then applied to wound, and the limb is encased in plaster, with the utmost care in the handling of the limb. The plaster is cut so that the side of incision is exposed for subsequent dressings in case of infection. If infection occurs, it is usually mild in character, the staphylococcus pyogenes or staphylococcus epidermis albus, as a rule, being the infecting organisms, and hence the infection involves only the superficial structures, and soon clears up upon evacuation of the pus. Deep infections are more serious, and sooner or later require removal of the plate. It should be borne in mind that, even if infection is present, the longer the plate remains the better the chance for union.

I feel that a brief mention should be made of the Parkhill clamp and its modifications. This clamp consists of two long screws that

are placed in either fragment through minute incisions, and then, after reduction of the fragments, are fastened by an external plate. A brief study will show that this method has all of the bad features of the open treatment with the bone-plates (with the exception that they can be removed without a secondary operation) and hardly any of the advantages of the open method. Morris has recently suggested nailing the fragments through a small canula, aided by a fluoroscopic screen, but the same objection applies to this as to the Parkhill clamp.

Now, in conclusion, I would say, given a fracture that is being treated by a general practitioner, without special surgical training, and who is indifferent to surgical cleanliness—here the proper treatment must be conceded, for, as before mentioned, the conservative treatment gives a fair functional result. On the other hand, a skilful surgeon, with a properly equipped operating-room, will get results by an operation with an ease and comfort to his peace of mind that is unknown to one who employs the conservative methods.

USE AND ABUSE OF STRYCHNIA.*

By W. E. REYNOLDS, Hopkinsville.

I know of no more important subject and none of greater interest to the medical profession than the one I now present.

And in the beginning, I wish to beg an apology for the few scattering ideas and want of language to express them in a way that some bright mind may be stimulated to analyze and glean the errors from this all important remedy. And while I feel my incompetency, and I notice how little that has been added to modern literature about a drug of so much importance and so generally and continuously used, I am encouraged to contribute my little mite, hoping that it may be as the characteristic "crumb upon the waters." So far as the physiological action of strychnia, no one has attempted to prove any other action than that of the spine. That it effects but little, if at all, the cerebral cortical centers, and while this should be a very important part of this subject; that if we know more of the physiological effects, we would be less liable to make the many mistakes, yet my time is so limited and the practical part so important that I will not attempt to discuss this part of the subject, but mention a few of the many troubles for which strychnia has been prescribed.

As a tonic, it fills its place equal to any member of the family and frequently the only one incorporated. As a stimulant it is one of the best, both heart and respiratory,

*Read before the Christian County Medical Society.

most lasting and constant. In gastro-intestinal troubles, known as tropid liver, when stools are of a light color and have an offensive odor, showing absence of bile, when the tongue is coated with thick fur, patient complains of headache, feebleness, loss of appetite, bad taste, small doses of strychnia will often act as well, if not better, than mercury. Some forms of epidemic diarrhoea and dysentery are frequently controlled by strychnia. Constipation, due to atony, is relieved by stimulating the muscular coat of the bowel. A valuable remedy in acute as well as chronic alcoholism, checks tremors and relieves delirium, lessens and removes the craving for stimulants. Is the sheet anchor in all antifeen habits of every description. Amaurosis, due to excessive use of alcohol or tobacco is particularly submissive to strychnia in more or less large doses. In progressive lead palsy, large dose of strychnia will check the progress of the disease. Morning sickness may be relieved by small doses. Eye strain from insufficiency of the ocular muscle is relieved by strychnia. It may be given with decided benefit in the doloreau and some other forms of neuralgia. In some forms of post-partum hemorrhage, nothing more reliable for contracting uterine muscles and keeping them contracted than strychnia. But by all means be sure you have no symptoms of puerperal eclampsia, for if you have, just so sure you will have convulsions, and with decided much more deleterious effects. Strychnia is often prescribed for paralysis due to apoplexy and I have know it being given in the acute stage, which as I see, we could only expect a greater blood pressure and more destruction of nerve and brain matter. In the chronic form, which is after all brain substance that has been destroyed have been absorbed with whatever nerve endings or roots that are included in this brain matter and nature has in spite of all we could do repaired this lesion, by pouring out a plastic lymph in and around this ruptured artery. I would like to ask the Doctor, what good he could expect of strychnia for a nerve that has dead roots and if there isn't some danger of another laceration of the tender repaired blood vessel? Now I have seen repairs completed weeks, months or a year, after a stroke of apoplexy. This is not nerves that have had the roots destroyed by the lesion, but those that have been pressed on by destructive matter and lymph poured out for protection and repairs. When after removal of this pressure by absorption then those nerves become again useful. I never give strychnia at all in the acute stage and if in the chronic stage, in very small doses. We are all in the habit of selecting strychnia as a stimulant in every case of anemia, loss of vitality, prostration or shock from any cause

without stopping to think of its physiological effects. My experience is, if you have or may have contractions or rigidity of the muscles, you had better let strychnia alone. I was once called to see a little boy that had a convulsion. The family was so excited that I could not get anything by which to base a diagnosis. I only had a patient prostrate, feeble, and frequent pulse. My first thought was a hypo of strychnia. Well in due time I had tonic contraction of the muscles and you would have to have been versed in mathematics to have told who had the most convulsions, me or my patient. In all forms of bowel trouble where we have an excessive amount of toxic poison absorbed with emaciation and a very feeble and frequent pulse, with contraction of muscles so closely resembling spinal meningitis that some of the most eminent physicians have mistaken the disease. In such cases strychnia would only add to your rigidity and contraction of muscles and lastly convulsions, and death, and instead of lessening the frequency and increasing the force of the heart's action, it is just the reverse. We have systolic action of the heart without a corresponding diastolic action, consequently the force and volume is compensated by frequency. I have my doubts about the efficiency of strychnia in typhoid fever of a low type with subsultus tendinum. These symptoms are *prima facie* evidence of great cerebral irritation and debility caused by absorption of toxic poison and want of pure blood supply to the brain. While I once heard a very distinguished physician say, as soon as he discovered prominent symptoms of typhoid fever he commenced strychnia. This would be a grave mistake in any disease, although this error is often made, as we would lose to a considerable extent the stimulating effect of smaller doses, and when we needed the stimulant, we would have to give more, and if for no other reason the exciting effects on nervous system by large doses. I think in nervous hysterical women, strychnia has been added to the prescriptions to either counteract the good effects of the drugs incorporated, or do harm. She may be, and most always is, anemic, yet her nerves are excited and if we give enough strychnia to effect her, it will be to increase the excited nerve. Strychnia should never be given during presence of acute symptoms of inflammation or congestion of either the spinal cord or of its meninges. Strychnia antedotes the poisonous effects of many useful drugs, as chloral, physostigma, cocaine, opium, etc. In opium poison, it is recommended by some physicians as a preference to belladonna. I think in opium poisoning, it is very good, but in all drugs that terminates the blood from the brain. We should be very careful that we do not get the

poisonous effects of strychnia before we get the beneficial effect, as I believe we get a more contracted effect on the heart in anemic brain with strychnia than benefits otherwise. So in trying to relieve the one poison, we get a worse poison of the other. Last but not least, I condemn the administration of strychnia before or preparatory to an anesthetic. If given in large enough doses, we will have rigidity of the muscles and carry symptoms all the way through the operation.

Much more could be said that I have not mentioned on this subject, but my time being limited, I will not worry you further. Hoping that you doctors may ravel this paper to a frazzle and glean what ever may be useful and if I shall have advanced one idea of useful knowledge, then with all the criticisms you may have alleged, I will have been more than repaid.

CRETINISM WITH REPORT OF A CASE.*

By G. C. RANKIN, Walton.

It is my purpose to present for your consideration a subject not new, but one that is ever interesting to us all; first, because of its rarity and of the certainty of the victim growing worse every day until relieved, and lastly because of its easy relief and treatment. Picture to yourself the sorrow, the grief and disappointment that is depicted upon the face of a mother when told that her child is an idiot and can not be cured.

The origin of the term cretinism is shrouded in obscurity. The probable derivation of the word seem to be from *cretina*, meaning stupid, or silly. Cretinism is a rare form of idiocy, usually occurring in infancy or early childhood. It may be either congenital or acquired, and sometimes occurs in adults when it should be called myxedema, the only difference between the two forms of the one disease being the age of the patient at the inception of the symptoms.

HISTORY.

Cretinism was first described by Plater in the year 1500. Hofer, afterward physician to the Austrian court, made some studies upon the subject in 1675. Fogge, in 1871 and 1874 reported numerous cases occurring in England, on the continent of Europe and America, showing the sporadic cretinism is not confined to any country.

ETIOLOGY.

It is now well established that this condition depends upon the absence of the internal secretion of the thyroid gland. The cause of the absence of this secretion is evidently some influence residing in the locality where

the disease prevailed. Heredity has doubtless something to do with its production in families but healthy individuals moving into the infected regions beget children who are, if not pure cretins, are goitrous and dull of intellect. The specific cause of cretinism though confined to fairly well defined locality has not been determined.

PATHOLOGY.

The pathological anatomy of cretinism is as variable as the cases examined are in the mental or physical manifestations. The skull is usually microcephalic, the bones are thickened. Premature ossification of the sphenobasilar bone was claimed by Virchow to be the principal abnormality of cretinism, preventing the proper growth of the base of the brain. The convolutions of the brain are of the most simple type and the sulci shallow and undefined.

SYMPTOMS.

The symptoms of cretinism in most cases make their appearance during the first year of life, but are sometimes so slight as not to be noticed until children are two or three years old, and exceptionally not until the seventh or eighth year. The general appearance of a cretin is so striking, and so characteristic that when once seen the disease can hardly be failed to be recognized. The body is greatly dwarfed and children of fifteen years are often only two or three feet in height. All the extremities, the fingers and toes, are short and thick. The subcutaneous tissue seems very thick and boggy but does not pit upon pressure like ordinary oedema. The facies is extremely characteristic. The head seems large for the body, the fontanel is open until the eighth or tenth year, the forehead is low and the base of the nose is broad, the lips are thick, the mouth usually open and the tongue usually slightly. The hair is coarse and straight and usually scanty. The teeth appear late and are apt to decay early. The abdomen is large, pendulous and resembles that of rickets. The skin is dry and harsh and eczema is common. One characteristic symptom being a subnormal temperature in a cretin who had pneumonia, all of the physical signs being present, but the temperature per rectum ranging from 95 to 99 throughout the course of the disease.

DIAGNOSIS.

This disease is not liable to be confused with any other but rickets. The low temperature, the facial expression, the skin eruption, and the dullness of intellect are enough to differentiate the two diseases.

PROGNOSIS.

Until within the last few years they have been considered hopeless. A sufficient num-

*Read before the Boone County Medical Society, November, 1911.

ber of cases have now been recorded to establish the fact that the thyroid extract is a specific remedy for this disease.

TREATMENT.

In as much as the etiology of cretinism is well established, it is not difficult to arrive at a proper system of treatment. If it is due to the absence of a substance, which normally is supplied by the thyroid glands, the scientific treatment would be to supply this necessity to the cretin, and thereby promote normal metabolism. Thyroid grafting has been done in a number of cases but without good results. Grafting has for its object permanent relief but only gave temporary results. Murray, first used subcutaneous injections of thyroid extracts or emulsions with good results, and a series of cases were reported by this method in the hands of numerous observers. Howitz, fed myxedemic patients with thyroids raw, partially cooked, or desiccated. The procedure is perfectly justifiable, not only by clinical results but by the fact that in lower animals and in the human embryo the thyroid glands furnishes a secretion to the alimentary canal by a duct opening at the foramen secum at the base of the tongue. The sheep's thyroid is habitually employed and is now an article of commerce in the form of various powders and tablets. When administering thyroid extracts it should be pushed to the physiological limit and a dose regulated according to the results desired. Parke Davis & Co., have on the market a thyroid preparation in powdered form, under the names of "Thyroids." By the use of this preparation I have been able to restore to health both mentally and physically, one unfortunate little girl whose history I now briefly give you:

Alma H., was brought to me by her mother for an eruption on her body in July, 1910.

Family History.—Father and mother both living and in good health. Has one infant brother in good health. No consumption, syphilis, or goitre in the family.

Personal History.—Age four years, sex, female, color, white. Had none of the diseases of childhood. Height 28½ inches; weight 30 pounds; head large for a child of her age; abdomen 23 inches; anterior fontanelle not closed; scanty coarse hair; eczematous eruptions; thick lips with tongue protruding; pedulous abdomen resembling that of rickets; lumbar lordosis; temperature per rectum 96.5. This child had never been able to walk without the aid of some one else, and had never been able to talk. She had at this time only four teeth. Childish games or plays of any kind were not fascinating to her, and she took no part in them.

Diagnosis: Cretinism.

Treatment was begun July 12, 1910, by

giving Parke Davis & Co.'s thyroids in one half grain doses twice daily. I had her brought back to my office once every two weeks in order that I might be able to recognize any improvement. On July 26 there was but little change, excepting a slight loss in weight. I then increased the dose to one-half grain three times a day. On August 9 the scales showed that she had lost three pounds in two weeks. Her mind was much brighter, appetite improved, rectal temperature normal, had cut two teeth and grown three-quarters of an inch in height. She was then brought back for examination September 8, with such marked improvement that I hardly recognized her. She had grown one inch and a half, making a total of two and one-quarter inches since the beginning of treatment. The edema had entirely disappeared and she was able to walk alone. Her mental condition did not seem to improve in proportion to her physical. To be able to illustrate the condition of this patient at the time treatment was instituted I present for your inspection a photograph. This photograph was taken the day before the beginning of treatment. The parents of this child being very ignorant I was unable to impress upon them the necessity of continual treatment, therefore I am not able to show you the photographs of this unfortunate child as she improved, as I had intended to do at the beginning of treatment.

It is the opinion of the essayist, based on this personal experience, and the recorded experience of others that by the careful use of this remedial agent, cretins can be completely transformed into intelligent men and women, and that no case, however grave, is beyond the reach of its marvelous influence.

PNEUMONIA.*

By J. P. WELLS, Meek.

As this is the season in which we have the greatest number of cases of pneumonia to treat, I desire to call the attention of the profession to the marvelous results achieved in its treatment by the use of creasotal.

I wish to state in the outset that whatever I may say in regard to pneumonia and its treatment by creasotal is based upon absolute facts, for I have kept no record of cases except those in which a positive diagnosis could readily be made from clinical symptoms and physical findings.

Having been taught that pneumonia was a self-limited disease—running its course regardless of treatment—and that the most we could hope to do for our patient was to get him in the best physical condition possible and by a proper dietary, supportive measures

*Read before the Pendleton County Medical Society.

—fresh air, etc.,—assist him to withstand its ravages until he had successfully passed the crisis. But now, we approach our pneumonia patients with a full assurance of faith that we have a remedy that comes as near being a specific as it is possible to get.

As to the etiology, pathology and diagnosis of pneumonia, I shall say nothing, for surely no man who bears the grand distinction of Doctor of Medicine would attempt to treat a disease that is so prevalent and with such a high rate of mortality as pneumonia without having a thorough knowledge of its pathology, diagnosis and treatment in all its forms and complications.

I shall confine my remarks especially to the treatment of pneumonia, and the results I have obtained by the use of creasotal. I have used it in the frank, open lobar pneumonias beginning its use in all its stages, also in the secondary lobar and broncho-pneumonias complicating other conditions; have used it in all ages and have never failed to obtain immediate and unmistakable results.

While it is true that there is no routine treatment for pneumonia—every case by reason of constitution, severity of the infection, complications, age, and whether it be primary or secondary, being a law unto itself; but what I wish to impress is the fact that creasotal is the remedy *par excellence* for pneumonia in any form, of any type of severity, at any stage and at any age. True, the diet, hygiene and general management of a patient suffering with pneumonia is of the utmost importance. He should be in a well-lighted, well-ventilated room—preferably by an open window; should have an easily digested, nutritious diet—bowels, kidneys and skin should be kept active; high temperature combated by hydrotherapeutic measures; excessive pain and restlessness quieted by hypodermic administrations of morphia et atropia. I employ counter irritation over entire chest by means of mustard plasters applied until skin is fiery red—three times a day—throughout the attack, and believe it a logical procedure. In sthenic cases when seen in the first stage, I invariably perform venesection, until pulse becomes soft and compressible, and have found it followed invariably by relief from pain, cough and dyspnoea. In those who are not so robust, use aconite until circulation is thoroughly impressed.

After this initial treatment I begin the administration of creasotal every four hour in 30 to 40 minim doses. Temperature usually drops from 103 1-2-104 1-2 to 100 or 99 1-2 degrees in 48 to 72 hours, pain ceases, rusty sputum stops, cough is no longer distressing, general appearance much improved, and convalescence is quickly established, and patient makes an uneventful recovery.

As a matter of course the earlier in the course of the disease the administration of creasotal is begun, the more decided and satisfactory will be the results.

A word about the preparation of creasotal used. The American product is no good, but the foreign product sold in this country by Farbenfabriken of Elbedfeld Co., New York City, is the only product that will give you the results outlined above.

SEPSIS AND ANTISEPSIS.*

By J. F. DAUGHERTY, Demossville.

This is an age of aseptic and antiseptic surgery. Hence modern surgery banishes septic inflammation and pus from her free wounds. We find ourselves able to control our surgical results. Pus in a clean cut wound means some error has been made in some part of the surgical procedure. But is this the case with septic surgery?

This great field of surgery appeals more closely to the general practitioner than any field with which we have to deal for more of these cases than any other fall into his hands. Therefore I shall discuss wound of exposed extremities, septic germs in great numbers and with irresistible virulence have entered the tissues and are working their destructive influence both locally and on the general system. The tissues locally are fighting a losing battle against the germs and the vital centers are suffering from the poisonous influence of the virulent toxins that are constantly being formed at the seat of germ activity. Surgery here becomes absolutely essential. First, the germs must be removed from the tissues or conditions must be rendered unfavorable to their continued action and, second the fighting power, the vital resistance, of the tissues and of the individual must be constantly maintained at the highest value.

When reference is made to the brilliant results of present day surgery it is usually to the aseptic results, but I am sure that results quite as definite and quite as positive have been attained in the field of septic surgery, and that we now treat our septic cases in a manner which is as highly superior to the older methods as are the methods of dealing with aseptic cases.

Septic conditions of the extremities may be divided into, (1) that condition known as cellulitis or blood poison, which may occur after the smallest scratch; (2) machine, gunshot wounds, and other wounds in which septic inflammation develops. These two varieties of septic wounds will be considered separately.

The first variety, known as an ordinary

*Read before the Pendleton County Medical Society.

felon, which develops from a puncture wound of the pulp of the finger, or from a hang nail either of which is so insignificant nine times out of ten patient will not remember receiving original injury, the finger becoming painful and slightly stiffened, redness appears at the site of the original injury and rapidly extends to the higher phalanges, swelling supervenes, both in the finger and in the hand, lines of redness run up the hand and arm, the patient is feverish and suffers from headache, loss of appetite. Pain soon becomes so severe he can not sleep and must walk the floor. What has taken place? Pathogenic germs have been introduced into the wound and have continued to multiply within the tissues. These germs in their process of growth have developed toxins which in turn act upon the walls of the capillaries and small veins of the tissues, the endothelial cells lining these vessels are paralyzed or degenerated, the cement substance between the cells become soft and the vessels "spring a leak," serum passes out into the tissues through these openings, white blood cells follow in large number and later red blood cells; this we call the exudate. From this cause the tissue space becomes swollen, the nerve endings are severely pressed upon and give pain and at last the blood stream is arrested. The toxins formed by the germs have acted upon all the tissues with which they have come in contact in the same manner they acted upon the endothelial cells and capillaries, and have caused every grade of degeneration up to death of the cells. When a retarded blood stream or a complete stasis of blood is added to the lesion it is a fact that these already dying cells are robbed of their nutrition and thereby of their power to fight the bacterial invasion. Now, at this stage of inflammatory process, it will be apparent that we have in a finger a tissue crowded full of serum, fibrin, red and white blood cells. Now as the exudate and tissue cells are badly degenerated, or entirely killed by the toxins of the bacteria and as the blood stream has become very slow or closed we are on the verge of a condition known as a peptonizing ferment which is regularly developed, coinciding with the pus forming germ. These ferments act upon the degenerated and necrotic tissue and dissolve them into one fluid mass which is called pus.

These germs do not confine themselves to this site but are transformed centrally through the lymphatic streams or along the plane of least resistance and progressively invade more tissue, sometimes with a rapidity that is alarming, as soon as the germs invade new tissue the same change as has been described continues. Lastly the toxins manufactured by the germs are taken up by the blood and are transformed to the vital cen-

ters of the body and produce the most grave constitutional symptoms.

TREATMENT.

Patients present themselves at almost every stage of the development of a felon, from the first pain at the site of injury to the point when almost all the tissue has been destroyed beneath the skin including the bone.

The invariable treatment for felon is free and liberal incision down to, but not necessarily through the periosteum. As felon is a painful affection many will apply for treatment before there is any pus formation, in cases of this kind make a free incision through the point most tender on pressure. When about to incise a finger, first apply 4 per cent. cocaine solution, begin by anesthetizing first the skin near the dorsum of the finger and using the "wheel method" of injection, continue till the area to be incised is rendered painless, or some surgeons claim to have good results from the use of ethyl chloride, but will say it has not proven satisfactory in my hands while if cocaine is properly used only the first prick of the needle is all that should be materially felt.

When incising a finger aim to get the point of tenderness but keep as near the side of the finger as possible to maintain the tactile sense of the finger. The first incision in an early case should extend to the periosteum; after the first incision is made and there is no relief from pain, another and larger should be made. When the infection involves the palm of the hand incision should be carried out as outlined above; such incisions are usually made along the line of the metacarpal bone, long and deep, use either cocaine or general anesthesia. The treatment should be, after incision, dressing with bichloride, carbolic acid or aluminum acetate lead solution, in ratio of 1 to 5000, 1 to 100 and 24 grain aluminum 38 grains lead acetate to one liter of water, respectively; use the solutions by bathing or by gauze wet with same and applied locally. Watch finger in healing process as by the tendon shortening a finger may become bent upon itself and remain so through life. This deformity can be prevented by keeping the finger on a small board during convalescence. So much for felon and palmar abscess.

The next subject we take up is that of diffuse cellulitis (infection) that takes place in various parts of the exposed extremities through scratches, bites of insects, blisters, etc., or through perceptible wounds and spread rapidly to other parts. These infections are either mild or severe according to number of germs of the streptococcic variety, the pathological lesion is a diffuse lymphangitis and cellulitis without any pus formation focus.

The redness is likely found to have its be-

ginning from a small scratch and rapidly spread, red lines run up the arm, the lymphatic glands are enlarged in axillary region, constitutional symptoms vary according to amount of streptococcic germs present and amount of tissue involved. Will illustrate by case Dr. Ed Wilson saw with me last winter: Woman, age 58 years, small scratch between knuckles of small and ring finger. When first seen temperature 104, wound painful, surrounded by reddened and swollen tissue, gradually extended up arm taking the nature of erysipelas, and died on the tenth day.

The appropriate treatment, if it is an open wound, is bichloride 1 to 2 or 5 mm., or if there is no perceptible wound use aluminum lead acetate sol., either hot or cold according to the will of the patient. Patient should be put to bed, bowels should be freely moved with calomel and salts, if in 10 or 12 hours patient is not improved, many deep, long incisions should be made in forearm to prevent infection. As stimulant, strychnia and whiskey are the main help, serum therapy may be tried.

The treatment of every accidental wound of the extremities, no matter how trivial, should be the same as an infected wound. In machine and many other kinds of wounds, dirt and debris should be removed from wound and use prophylaxis. Infection of wounds like the above named may be divided into (a) mild infected wound only a small area around it involved, and (b) an infection of entire wound.

In the first variety the patient will have a slight fever, 99 to 100 degrees. To treat this class of wound, remove dressing and use bichloride dressing after opening up the wound freely.

For severe wound infection, where fever is higher than in light infection, more prostration, dry tongue, chilly sensation, pulse fast, fast breathing, open up the wound, remove sutures, clean out with bichloride and use as often as needed, alternating with carbolic acid solution or lead and aluminum. Internally use supportive treatment.

SETICÆMIA.

This is fortunately an extremely rare complication of operative wounds and is seen mostly in those wounds where infection has been carried in at the time of injury and has gained headway before surgical aid had been sought. The symptoms of this severe form of wound infection comes on in a few hours after a traumatic wound or one just described under the heading of infected wounds. The condition usually begins with chill, elevation of temperature, increasing pulse rate and pain in wound and neighboring lymphatic glands. There is loss of appetite, nausea, vomiting, dry coated tongue, remittent type

of fever 99 to 104 degrees, nocturnal perspiration, which may be profuse; patient becomes weak and emaciated, joints become painful, metastatic abscess may occur in any part of the body, developing very rapidly.

TREATMENT.

Treat wound as above outlined. Give albuminous foods, large quantities of water, urotropin to open kidneys, move bowels with salines, salicylic acid or better, salicylic soda and quinine to counteract the septic process.

TETANUS.

This affection is likely to occur in any wound of the exposed extremities and more particularly in punctured wound made near barnyard manure. It often occurs after wounds made with toy pistols, blank cartridges, etc. When such wounds present themselves to us we should cauterize them with nitric acid or chloride of zinc 10 per cent. solution.

The next subject, and the last I shall mention, is dog bites. Being so much alarm from hydrophobia at the present day, this form of wound should receive more than passing notice. When a wound of this character is received it should be at once cauterized with nitrate acid or zinc chloride. Dog should be penned up for a few days and if he be rabid symptoms of such disease will present themselves in a few days and the dog will die in ample time to begin Pasteur treatment for hydrophobia. If the dog is killed as is often the case, remove the head and as much of the spinal cord as can be obtained and send it to the State Bacteriologist, Bowling Green, Ky., for examination. A great number of wounds received from pet animals need not be cauterized, but will do well if treated antiseptically.

NEEDS FOR OUR KENTUCKY ASYLUMS FOR THE INSANE.*

By R. W. WOOD, Lexington.

Life with its sorrows shows none so sorrowing to the human family as the mind dethroned. The causes are many that the state must stand sponsor. But then this report is not on the causes or treatment of insane any more than is necessary to show the present as well as future needs in asylum or state hospital. True a bad workman complains of his tools and I being one of the workmen get full benefit from the public for failure to return a greater percentage to their families, but if you will realize that the family physician has failed in result and no provision in the law to give us the history from physicians who have had patient under observation perhaps years. No lunacy commission. No physician necessary at the court where this unfortunate is

*Read before the Boyle County Medical Society.

tried. If a physician is called as a witness no provision is made for expert testimony, a copy of which should accompany every patient to the asylum. This failure in the law is one of the greatest drawbacks to asylum physicians as well as to keeping statistical records for study of causes for insanity that the family physician may, through them, better advise the homes. The lack of money bars many plans that the present management of asylums would like to inaugurate: Hydro-therapy, electro-therapy, physical culture under a trained physician, better segregation of patients, etc.

Now to the needs of asylums. I may ask too much of the State but if the medical profession will study this question closely I believe they will agree with me in great part in establishing one central psychological hospital where patients shall first go to remain not less than thirty days or more than ninety days. This hospital shall be a model in every way, with perfect laboratory, hydro-therapy, etc. With abundant number of physicians and nurses that each patient shall have special personal notice as to history, both personal and family, with all social and business of the patient's life. Now, after this perfect examination and patient does not recover in the thirty days he may be sent to the asylum or hospital located in his district. He can, however, be kept for ninety days but must be transferred or discharged at the end of this time.

This central hospital is to receive any one on their request with certificate of two physicians and payment in advance of fees for ninety days. Any unused part to be returned to patient when he goes home.

The cost, however, is to be thirty dollars per month instead of the present sum of only twelve and one-half dollars per month. Thus many of limited means could be treated without the necessity of a trial at court. If the necessity of trial at court at least two physicians must be called, whose duty it will be to thoroughly examine patient and family history and the findings of these physicians must be put in writing and sent with patient to this central hospital where a more complete examination including the laboratory examination will be held. When patient is to be sent to district hospital a copy of all records must accompany him. True many of these measure may be added to the present asylums and I hope they will be, but first let us put up this model central psychological hospital for three hundred and fifty to five hundred patients and prove the advantage then the people through the legislature will be willing to grant the appropriation needed for the present asylums which has so long been withheld. Stop one moment and think the sum

of twelve and one-half dollars per month, per patient, paying for the food, clothing, heat, lights, housing, bedding, physician and nurses. In fact every necessity for a patient at the magnificent sum of twelve and one-half dollars per month and everything at the present prices. I am glad to say that the past three years has seen vast improvement in the asylums of Kentucky, but oh, how many things are to be done and can be done but for lack of money. I ask the profession, can you do all you would love to do with forty patients at the point of death or convalescence from some physical disability and two hundred others who are insane and with many minor physical disabilities and yet this is the condition of the Eastern Kentucky Asylum for the Insane and I feel sure that the same conditions present themselves to physicians at the other asylums of the State. Is this not penny wise and pound foolish on the part of any state that does not furnish these necessities? *

Segregation of patients is one of the prime necessities of any asylum, yet owing to construction at the Eastern Kentucky Asylum it is impossible for the present management to properly classify patients. Building constructed eighty-four years ago and still in use. Others built under the crude sanitary idea before the Civil War. But then the pressing needs at asylums will be no doubt brought out by the Board of Control and the superintendents of asylums to the attention of the people and legislature. These two questions I wish to leave with the medical profession—the Lunacy Commission with two physicians as witnesses and examination of every patient and this central psychological hospital. You may differ with me, then speak out for there surely is need.

After a study of these questions for nearly three years I would say with a conservative board an appropriation of from fifty to sixty cents (jailers receive seventy-five cents per day for feeding their prisoners) per day, per patient, for district hospitals and one dollar per day for central hospital this work could be carried on in a high class way. Citizens saved, homes made happy and Kentucky blessed.

Iodin in Exanthematous Typhus.—Uftogeanin-reports fourteen cases which added to Jaworsky's forty-one brings to fifty-five the number of exanthematous typhus patients treated with tincture of iodine internally, three or four drops three or four times a day, taken in red wine. The disease was unmistakably modified by the medication and evidently much for the better in the entire group, he says.

PAIN AND ITS SIGNIFICANCE.*

By A. M. HAYDEN, Evansville, Indiana.

I am delighted to have the opportunity and honor of addressing you on this occasion. I understand that this is an open medical meeting to which are invited the bar, clergy, laity and all who may be interested; and in selecting a topic for discussion I have tried to select one, that unfortunately we each will sooner or later be seriously and vitally interested in. The subject is "Pain and Its Significance."

During my remarks on the subject of pain I will refer particularly to a few of the diseases that are characterized by an unusual amount of pain. While doing this I may digress somewhat from the main subject of the paper.

Pain is bodily suffering due to irritation of sensory nerves or to changes in the central nervous system. Pain in itself is not a menace to life and should not be so regarded, but looked upon as a friendly warning of a possible approach of diseases that might prove fatal if the conditions of the system responsible for the pain are not removed by judicious management and treatment.

The nerve terminals act as sentinels to guard the body from external violence, just as pickets are thrown out around an army to guard it from surprises and destruction. Pain is not always located in the organ that is responsible for its existence, but frequently in organs remote from the seat of pain. This should always be borne in mind in seeking remedies for its removal.

For instance, migraine or headache, is often due directly to a disordered stomach, disturbed conditions of the circulation, abnormal increase or decrease of blood supply to brain, a deteriorated or vicious blood supply to brain.

To relieve headache caused by a disordered stomach our remedies should be directed to that organ. If the pain is due to disturbed circulation, the cause should be searched for and removed if possible. This disturbed circulation may be due to a fever, in this case we determine its nature whether typhoid, malarial or due to some organic lesion such as tuberculosis, abscess or some local inflammatory action in some organ of the body. In any of these cases appropriate remedies should be applied.

A poisoned or vicious blood is often due to organic lesions of the kidney such as nephritis commonly known as Bright's disease. This disease disables the kidneys and renders them incompetent to perform their normal functions, which is to eliminate through the

urine the poisonous waste matter of the body. The principal part being uric acid. This substance being retained in the blood produces uremic poisoning resulting in headache and later convulsions and death.

Notwithstanding all these various and widely different cause of pain in the head or headache some of the laity believe they can go to a near-by drug store and secure a sure cure headache powder that will cure any pain in the head. In case they happen to get relief after taking one of these powders they are quite ready to recommend it to all their friends who may be suffering with pains in the head, and accompany such recommendation with a guarantee for a sure cure. Now any one who will stop to think for himself just a little bit will readily see how absurd it is to presume for a moment that there could be a ready made remedy that would answer for a cure for all these different forms of headache or pain in the head produced by so many and widely varied causes. They at once would understand that if there was such a remedy it must necessarily contain what is commonly called dope. This being the case they should also know that any treatment containing opiates or dope and not directed to the cause of the disease must necessarily be injurious.

It is well known to the medical profession that the earliest symptoms of hip-joint disease is a pain in the knee. The patient will complain of a persistent pain in the knee and will endeavor to associate the cause of it with some accident or injury it has received and will often persuade himself that he remembers some slight bump that he has given it, with this belief he goes on waiting for it to recover, considering it a small matter. Finally he decides it is not improving as fast as it should and consults a surgeon, who finds the hip joint so badly disorganized by organic disease that he will be a hopeless cripple in spite of all the surgeon can do. I would advise those who have children, in case any of them complain of a persistent pain in the knee, to at once consult a physician or surgeon. I say children, because this disease occurs more frequently during adolescence than any other period of life. While hip disease is very intractable and often results in crippling its victims, most cases if taken in their incipency and properly treated by extension, will terminate in a permanent cure without deformity.

The pains in appendicitis are often referred to the epigastric or stomach region, the umbilical region, and sometimes in the left side, which, of course, is misleading to the laity and often to the inexperienced physician. In this disease, however, in a day or two the pain subsides to a soreness in the right

*Read before the Henderson County Medical Society.

side over the region of the appendix. Too much reliance must not be placed on the pain as a diagnostic asset in this particular disease. While you may have extreme pain at the onset this often subsides in a few hours and leads the patient, as well as the physician, to believe that he is convalescent, while in fact, the disease is rapidly progressing toward perforations or gangrene of the appendix. This, of course, is a very serious complication. In fact a sudden cessation of pain in these cases often indicates gangrene of the appendix, the parts dying, cease to be sensitive and no longer cause pain, even though the disease is progressing. Patients suffering with appendicitis usually have a great deal of pain and are insistent upon having some remedy, such as opiates, for immediate relief. This, as a rule, is a very dangerous thing to do because it lulls the pain, masks the symptoms and renders it impossible for the physician to know whether the patient is progressing favorably or continuing to grow worse. It creates a sense of security and well-being in the patient that often causes him to delay an operation until it is too late to be of any value to him.

Gall stone pain begins suddenly, at the moment a stone passes from the gall bladder into the cystic duct. At this time the patient is seized with a piercing, agonizing pain in the region of the gall bladder radiating over the abdomen and extending back to a point under the right shoulder blade. The abdominal muscles are cramped and tender; there is nausea and vomiting, a weak pulse, cool skin, pale, distorted anxious face and maybe fainting, spasmodic trembling chills or convulsions. The paroxysm continues for an hour or two to several days with remissions, but entire relief is not afforded until the stone reaches the duodenum or drops back into the gall bladder, when pain suddenly ceases. Jaundice usually follows the paroxysm of pain. When the calculi reaches the intestines or gall bladder the pain, nausea and vomiting cease, the appetite returns and the jaundice soon disappears. Should the calculi become impacted or from any reason fail to leave the gall bladder, a resulting cholecystitis follows and an operation removing the stone or stones and draining the gall bladder is indicated, and this is the only remedy that gives permanent relief.

Another fact in connection with gall stone trouble that should be borne in mind, is, that the prolonged irritation of their presence results in at least 4 per cent. of the cases terminating in cancer of the gall bladder and liver. This should all be considered in connection with all pain, trouble and inconvenience that the constant suffering caused by their mere presence. This should all be explained to the

patient suffering with gall stones when advising him concerning his condition.

While on the subject of cancer I will add that you are all probably aware of the fact that it is one of the most painful diseases the human family is heir to, and most people believe it to be absolutely incurable. My opinion is, that there is a time in every case when cancers can be cured by a radical operation. The unfortunate phase of cancer is, that the surgeon seldom sees a case during this period of the disease. The patient not considering it worth while to consult a physician until it begins to pain him and cause inconvenience. Many people go around for many years with a large mole or wart on their body. This should be removed for it is very prone to degenerate into an epithelioma or cancer. After this has taken place the patient begins to suffer pain and eventually seek said of the surgeon and has it removed.

He often has, as a result of the delay, a recurrence, this recurrence is due to the fact that the time for a radical cure had forever passed at the time of operation. To-day there are hundreds of women in the United States with small apparently harmless tumors, or lumps, in their breasts who never think of having them removed or even consulting a surgeon in regard to it, simply because they are suffering no inconvenience or pain from their presence. Many times my position has been assailed and I accused of wanting a fee, when advising a patient to have them operated upon. Now I wish to say that every abnormal growth, or tumor, situated in the human body is a menace to life and should be removed.

If it has not already degenerated into cancer then you remove forever the possibility of its ever becoming one at practically no risk. Quite often I have removed from the human breast what appeared to be a small benign or harmless tumor in which a careful microscopic examination revealed cancer cells. In these cases, the patient nor the physician had even suspected the possible existence of cancer.

In conclusion it would be well for one suffering with persistent headache to consult a physician instead of trying to cure himself by the continued use of headache powders, or some form of dope, which they usually contain. Persons having frequent attacks of severe pain in the region of the stomach even though of short duration, attacks of cramping in the bowels, or pain in the region of the knee that is persistent, would act wisely to consult their family physician.

EDITORIAL

UNRELIABLE MEDICAL JOURNALS.

A recent editorial in the *Journal A. M. A.*, (Jan. 6, 1912, p. 36) emphasizes the fact that many medical journals are run in the interests of their advertisers rather than those of the readers. Regarding the "conspiracy of silence," which in the past has kept out of lay papers anything that might be detrimental to the patent medicine advertisements therein, it is said that "one of the most powerful chapters in the Great American Fraud series was that entitled, 'The 'Patent-Medicine' Conspiracy against the Freedom of the Press,'" by Mr. Mark Sullivan. Therein it was shown that the twenty millions or more dollars spent annually by the 'patent-medicine' manufacturers of the United States was expended not merely for what went into the newspapers as advertisements, but for what was kept out of the newspapers as news."

It is explained that newspapers when receiving contracts for patent-medicine advertisements were obliged to sign an agreement not to publish anything that might be detrimental to the interests of their advertisers and that as a result reports of poisonings or deaths due to patent medicines would be suppressed.

Exactly the same conditions exist in medical journalism as in lay journalism. Not altogether the same either. Possibly because the sums of money involved are not as large or for some other reason, the "silence clause," as such, has not, we believe, been brought into use in making advertising contracts with medical journals. But so far as the actual working of the matter is concerned it might as well have been. For although the fraud and chicanery connected with the so-called ethical proprietary business have been repeatedly exposed, practically none of the self-styled in-

dependent medical journals have given their readers any information regarding the matter. In the medical field, then the conspiracy of silence has been just as effective as in the non-medical—and the injury to the public probably almost as great.

The editorial then relates that some years ago in reviewing a report of the "Commission for the Study and Treatment of Anemia in Porto Rico" it was suggested that the day of blind reliance on iron, quinin and tonics in general in the treatment of anemic conditions was past. To this the exploiters of a proprietary iron preparation (Pepto-Mangen, Gude) protested vigorously against the publication of statements which would damage the sale of their product. The editorial acknowledges that "It was inconsistent for *The Journal*, which was exposing mendacity, editorially, to accept the advertisement of a preparation that was sold under mendacious claims." This incident is recalled to make evident the uselessness of expecting medical journals whose very existence—in some instances—practically depends on advertising contracts of proprietary manufacturers to tell the truth in their reading pages when such truth is against the interests of their advertisers.

That these facts obtained widely is further supported by reference to the suppression by practically all the so-called independent medical journals of the valuable reports regarding proprietary medicines which have been given out by the Council on Pharmacy and Chemistry because the products considered in these reports have been good advertisers.

We take this occasion to say that this *JOURNAL* does not belong to the "independent" class but that instead it depends on the medical profession for its existence and that to merit the continued support of the profession it presents those matters which physicians should know.

PASTEURIZED MILK.

No layman has ever accomplished much more for preventive medicine than has the Hon. Nathan Straus, the distinguished philanthropist of New York City. Like every other man who has done anything for preventive medicine, he has been hounded and misrepresented by the cranks and the misguided, and it is a pleasure to see him hit straight out from the shoulder at some of these as he does in the attached communication. After the publication of this challenge, it is up to the objectors to either put up or shut up.

"To the Editor:

"In the efforts that are being made to protect the babies from milk-borne diseases such as tuberculosis, typhoid and scarlet fevers, diphtheria, sore throat and summer complaint, the well considered policy of the Public Health Service and of the foremost health officers of the country is seriously hindered by attacks based upon ignorance.

"The statement is repeated with assurance, without proof, that the use of pasteurized milk causes rickets, scurvy and anaemia. People are scared by these outcries into exposing their babies to infectious diseases, and the lives of helpless little ones are forfeit.

"It does not undo the harm by showing that the Public Health Service after exhaustive investigation, declared that 'Pasteurization prevents much sickness and saves many lives,' and proves that the process does not impair the taste, digestibility or nutritive qualities of the milk.

"It does not protect the babies from reckless misrepresentation for me to point out that in feeding 25,000 babies with pasteurized milk through my infant milk depots in New York City alone, never has one case of scurvy or rickets developed. Nor does it still the voice of mischief to cite the experience of Dr. Variot, in Paris, who fed 13,000 babies on sterilized milk without causing these diseases.

"Several years ago when a famous physician who opposes anti-toxin and vaccination, raised this cry of scurvy and rickets, I publicly challenged him to produce one case caused by pasteurized milk, and he subsided.

"But the mischief of this warfare on the babies goes on, and many lives are sacrificed. If it could be known how many babies perish through their parents being misled by such statements made through recklessness or ignorance, editors would close their columns to such outbursts as they generally do to the tirades of fanatics who oppose vaccination.

"In order to bring this issue to an end, I offer through you \$1,000 for any case of scurvy or rickets or anaemia caused by feeding a baby with properly pasteurized milk.

"If any such case is alleged in answer to this challenge, I will leave the determination

of the facts to Dr. Rupert Blue, Surgeon General; Dr. M. J. Rosenau, Professor of Hygiene and Preventive Medicine at Harvard, and Dr. John F. Anderson, director of the Hygienic Laboratory at Washington, or any jury that they may choose."

"THE CASE OF BECKY."

On the 25th of January, this year, at Mauley's Theatre in Louisville, Davis Belasco presented "The Case of Becky," with Miss Frances Starr in the title role. Miss Starr was assisted by a little company of six players of unusual merit and ability. The play is a modern one, and deals with the question of dissociation or dual personality in hysteria. The popular conception of which is embodied in the idea of "Dr. Jekyll and Mr. Hyde."

The action of the play takes place at the home, or sanatorium of one Dr. Emerson, a specialist on nervous and mental diseases, a physician modern enough to realize the psychological side of the so-called "function" diseases of the nervous system. In reality, the play in its conception of the pathogenesis of hysteria is far in advance of a great many of the text books now upon the market.

The curtain arises, disclosing the elegant office of Dr. Emerson, beautifully furnished, and with all the modern case record histories, etc., so needful to an accurate understanding of cases. The second act, likewise takes place with this as the background, while the third act, the culminating and melodramatic one, occurs in his laboratory, which is in reality a psychological laboratory.

The animus of this editorial is to call attention to a well known fact that the doctor of stage life, is as a rule, grossly misrepresented, being usually a travesty upon the profession, and at best either an arrant knave or a blithering fool. With two decades and a half, of what I am constrained to believe is a discerning and appreciative view of the drama, I am glad to state, that to my mind, Mr. Albert Brunning's rendition of the character Dr. Emerson is the best acted physician that I have ever seen upon any stage. He is *par excellence*, the gentleman; high toned, modest, learned, devoted to his patients and his profession. He makes a thoughtful, dignified, real physician, the best type of specialist, the best type of man, and what is so essential and so necessary to one in his position, he does not lack that all essential qualification of real and genuine humor. It is indeed to be regretted, nay a thousand pities, that there are not more Dr. Emerson's and Mr. Brunings, to portray the medical fraternity as it is portrayed in this play. The medical profession is indeed indebted to Mr. Brunning for his interpretation of one of its members. It

looks like it were a gift of the giftie to let us see ourselves as others should see us.

Look upon that picture, and then upon this. Charles Dalton, nearly always good at anything he attempts, makes of Professor Balzamo a professional hypnotist, the typical and despicable quack. He plays Balzamo's blatant, breezy, brazen ego-mania, in a way that is masterly, for Balzamo, like all of his kind, fattens coldly on the weaknesses and miseries of humanity. Loud, coarse, and lacking in all the finer niceties of the conventional, ethical and cultured physician, Balzamo stands out as a character not likely to be forgotten in many years to come.

Miss Frances Starr has a most difficult role in that of Dorothy the good, and Becky, the bad. It is no easy proposition to transfer to acts, the psychology of hysteria, but this she does in most excellent fashion, though of course, to the reflective mind of one, who like myself, makes a special study of these conditions and whose life is thrown with them constantly, would consider at times, just a little overdrawn, but this is perhaps due to the fact that the pathogenic material with which she is working is so familiar. The layman would not labor under such a handicap.

Subtle exhibitions of latent character, the tinge of sexuality that is so delicately and subtly shown, would require one familiar with the Freudian doctrines to appreciate fully its subtle niceties and the remarkable capacity of her acting; a hard part, well played.

The other members of the company give a finished rendition of the minor parts. The total *ensemble* makes one hope we may see this group of players attempt some other psychological stage work along this line. In conclusion, I feel that Mr. Edward Locke, the author of the play, has rendered plain a most difficult subject, and taken "all in all," has produced a play of unusual merit. "Here's hoping that he may live long," and ever bear to the medical profession the same kindly feelings that he has put in his character of Dr. Emerson, and it is to be hoped that the medical profession will in their turn, feel gratitude toward the man, who has pictured them in what might be justly termed, their true colors.

CURRAN POPE.

Iodin in Exanthematous Typhus.—Uftageaninoff reports fourteen cases which added to Jaworowsky's forty-one brings to fifty-five the number of exanthematous typhus patients treated with tincture of iodin internally, three or four drops three or four times a day, taken in red wine. The disease was unmistakably modified by the medication and evidently much for the better in the entire group, he says.

IN DEPRECATION OF THE NEGLECT IN GENERAL BY PHYSICIANS OF THE MEDICINAL TREATMENT OF DISEASE.

I.—THE TREATMENT OF MALARIAL DISEASES.

(CONTINUED).

Dr. Austin Flint, Sr., appears to be the only American text-book writer of prominence to accentuate this feature of our indigenous tertian infections. Few indeed of current manuals of practical medicine refer to it, although there is occasionally repeated in them popular impressions about relapses on the *seventh* day. I cannot but ascribe this to Hebraical prejudices and predispositions ascribable to the Bible. I can, on the other hand, base the twenty-first day relapses upon definite facts within my own experience; and I believe that they are explicable by biological factors relating to the action of the *Plasmodium malariae*. I hope and expect that C. C. Bass's cultivation of this germ will aid us greatly in elucidating this point upon average human beings.

In my work aboard cruising men-of-war, I have been able to prove fairly exactly that *twenty-one days* is the incubation period in man of the tertian organism. This was true of my own infection, to which I have referred above, at Palatka, Florida. Furthermore, I observed two men-of-warships that were infected at Nagasaki, Japan, in June, 1895, one of whom was a robust young seaman moderately addicted to the abuse of alcohol, and the other a middle-aged but vigorous negro whose rating was that of captain of the hold. Our vessel came from Newchang (Yingko), China, in April, 1895, to Shanghai and proceeded thence to Yokohama, Japan, stopping at Nagasaki for about two days. Both of the men affected, who showed the only cases of malaria on board at or near that time, had spent the same night ashore in Nagasaki; each of them had his initial chill on the same day; and each of them relapsed, in spite of more vigorous treatment than is usually sanctioned by teachers of medicine, on the twenty-first day thereafter; and the captain of the hold relapsed again under my treatment, although it sufficed in the case of his white fellow-sufferer. I left the ship on a special detail before the expiration of another interval; but I commended him especially to my successor. When I saw him again at the U. S. Naval Hospital at Cavite, P. I., in 1902 under treatment for a big axillary abscess, he told me that he had had three more chills after we had parted company; but he could not be lucid about the intervals of time between them, and I have never made occasion to investigate the official records upon this point.

The Navy surgeon that had fallen heir to his case died suddenly within eighteen months of this incident.

I wish to be as emphatic as possible about not employing quinine, except as I have tried to indicate above. Except at the approach of paroxysms, other antiperiodics than quinine should be used, for the reason, it appears to me, that quinine is ineffectual against this plasmodium at most other times than when sporulation is imminent. Some definite facts are available, to support the view that its continued administration in from small to medium doses (say from three to five grains, t. i. d.) invites habituation of the malaria organism to it, thus rendering persons with latent infection liable to outbreak upon marked changes in their habits or in their environs. I have found arsenic in the form of Fowler's solution very effective as an interim antimalarial and as a tonic; but, in cases where the patients are beyond middle age, or debilitated or forced by their environments to use much vegetable food, I prefer pure capicum, which had great vogue before the days of Countess del Chincon, presumably by reason of its obviously strong indication according to the doctrine of *opposite impressions*—the slanderous *allopathy* of the persistent detractors of regular medicine. I have found it best for such a person to take as much of it as he will after meals in the form of fresh pills made up with bread-crumbs. I have often employed a drachm a day thus, and I have myself frequently taken half of this quantity at a single dose without notable inconvenience. Occasionally, its rather pronounced aphrodisiac effects are unmistakably exhibited.

I should have been glad to have felt myself free to leave this subject without challenging further *ex cathedra dicta* regarding it. But I must say regarding C. F. Craig's statement, in 'Osler's Modern Medicine', that fifteen grains per diem of quinine is sufficient to cure intermittent fevers, that it does not comport at all with my experience nor with that of few, if any, of my colleagues. As this, in my opinion, very dangerous error occurs in close proximity to the further misstatements that the sulphate of quinine and the dihydrochloride (bimuriate) are the two most valuable salts of this alkaloid and that the sulphate is soluble in 1 to 9 (*sic*) parts of water, we benighted Southerners that have endured malaria as almost as necessary an evil as the doctrine of protection or as national pension grafting, arise from our efforts to modernize our medical work with feelings and with a general mental state akin to those of an aroused somnambulist. Dr. Craig's underestimate of the dosage necessary for curing aestivo-autumnal fever will be referred to herein-

after. But I am disinclined to omit a tribute to the persistency of a Kentucky statesman, who was reared and who worked in this section of this State, in defeating a strong lobby influence after a long struggle by passing his measure through the Congress, to remove the duty that had hitherto been levied on quinine. "Quinine Jim" McKenzie should be a name to awake responsive memories in the South ages after every trace of the Weightman millions that were accumulated directly by means of the tariff will have disappeared from the earth—and from New Jersey and its politics as well!

I have had next to no experience with quartan infections; hence, I shall omit discussing their management. I feel sure that they are so uncommon as to be virtually negligible in the Middle States at this period. Only a case or two of it figures in the American work in the Canal Zone, according to the statement to me of a Yale medical graduate, which he made in November, 1909. W. F. A.

(To be continued.)

SCIENTIFIC EDITORIALS.

WHAT IS THE MATTER WITH THE MEDICAL PROFESSION?

Judging from the numerous articles in medical journals pro and con on the "division of fees," and resolutions passed by many medical societies discountenancing this practice, the question is being freely asked "What is the matter with the medical profession?" Is it degenerating to the plain of commercialism, or are its aims, standards and ideals being elevated?

American Medicine of Dec. 11th, 1911, in an editorial, makes some pointed and valuable comments which are worthy of careful consideration.

The medical profession has emerged from superstition and mysticism into modern accuracy and truth, conscious of its great duty of relieving suffering. There is a psychological influence that gives a certain personal responsibility of the obligations of each general practitioner which must be felt to be realized. This influence makes him look on his work differently than merely a work for dollars. Let him experience the satisfaction following the saving of a life, or relieving great suffering, then he can grasp the nobler meaning of the work.

Judging from the progress made in service to humanity, and scientific attainments, it can well be said, "the medical profession is all right." But the medical profession, must not be confounded with the individual physician. We cannot afford to be blind to the shortcomings of an occasional practitioner. To

deny that certain evils exist and many physicians are losing the benefits that should be theirs, is carrying optimism too far.

Every practitioner knows there is something wrong in the profession in certain places. This Journal does not believe there is an overcrowding in the profession which was threatened years ago. It is known that the medical colleges are graduating fewer numbers, which is due, to some measure, the elevating standards of the schools; and further, that the profession is offering less pecuniary benefits. But the problems of *premature specialists* in the various branches of medicine are more serious problems. This is truly a day of specialism, and specialism based on efficiency, nothing can be said against, but there has been an enormous increase in premature specialism. Young graduates go to Europe for a few months study in the clinics and come home purporting to be full fledged surgeons or eye, ear, nose and throat specialists. Or others take a 6 weeks course and call themselves competent. "Every capable surgeon knows only too well the harm that is being done by premature surgeons, men who have no more moral right to be practicing surgery than a carpenter." The medical practice suffers by the reason of the failures of incompetent surgeons. Many of these have believed themselves competent. Colleges have been much to blame, for they have not tried to correct the idea that their diplomas are certificates of merit and individual ability, when they are only certificates of completion of certain courses of study. Then the State license has added its share of extending the evil by granting the unrestricted right to perform any operation or undertake anything in any medical practice, if the candidate can answer 75 per cent. of the questions asked. A written test is certainly no test of a surgeon's ability, yet the state will grant him a license as a surgeon, obstetrician, or specialist. A lack of discrimination on the part of the people, is an important factor in the situation. "A pleasing personality, social distinction, church relation, personal appearance and countless other irrelevant considerations have led individuals to place themselves under a doctor's care." No thought is given to his training or experience. The owner of a valuable animal would seek the best veterinary if it were sick but he does not use the same discriminating care in selecting a physician for his child." Unfortunately a great many people will go on trusting themselves in the hands of the surgeon or specialist who strikes their fancy, irrespective of ability or experience. Sooner or later the *State* will require that the surgeon and specialist but measure up not only to a knowledge of the subjects but to efficiency.

Another evil though by no means so important as premature specialism is the tendency to disregard therapeutic or curative measures. True it is that our knowledge of physiology, pathology, appreciation of the value of hygiene, diet, and preventive measures, have grown, also a greater realizing of the importance of the vital forces; but they have created a belief among many that these are all sufficient and the results often attributed to therapeutic measures are due entirely to the organic activity.

"The pendulum of thought always swings to extremes" and it was expected that the absolute confidence in remedial agents of the last two decades should be followed by the opposite or "therapeutic nihilism." "It is disconcerting to the student of mankind that the human mind can reverse itself as often as it does."

Certainly the extent of drug nihilism has not resulted in the laity consulting the medical men more freely, but there has been a turning of the people to quacks, etc. And the doctors must thank themselves for the quarrel with the measures they have taught the public to use. Drugs and remedial agents have their limitations as well as their uses. "It may be true that in the past we have exalted drugs too highly and placed too little dependence on bodily powers. But recognition of the mistake does not make it necessary to make another." Used wisely, drugs can give material aid in correcting abnormal condition in the body. Physicians will never place the blind trust in drugs as formerly, but will demand that in addition to medication, rational eating and hygienic living must be observed.

J. A. STUCKY.

Test for Albumose in the Urine.—Fittipaldi mixes the specimen of urine with six times the amount of alcohol. The next day the alcohol is decanted, the sediment dissolved in as little as possible of a solution of sodium hydroxid (31 to 32 per cent.), and the alkaline solution is tested with the ammoniacal solution of nickel. This reagent is a mixture of equal parts ammonia water and a 5 per cent. solution of nickel sulphate. It is bluish, but when a drop of this reagent is added to the alkaline mixture above, the tint changes to orange in the presence of albumose or peptone. The method can be applied to the blood, first heating to boiling after it has been well mixed with animal charcoal (10 or 20 gm. to 10 or 20 c.c. of blood). The filtrate after cooling is mixed with six times the amount of alcohol as above. This method does not require preliminary removal of the albumin from urine and there is no possibility of confusion with albumin, as the latter never gives the orange reaction.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicines. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A. Council on Pharmacy and Chemistry for inclusion with "New and Non-official Remedies." Under "Reform in Medicines" appear matters tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

RELIABLE MEDICINES.

Articles found eligible by the Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies."

Propaesin is propyl aminobenzoate $C_6H_5NH.COO(C_3H_7)$ 1:4. It is a fine colorless, odorless nearly tasteless powder, which produces numbness when placed on the tongue. It is almost insoluble in water but soluble in alcohol, chloroform and ether. Said to be stronger than ethyl aminobenzoate (anesthesin). Used in the treatment of gastralgia, gastric ulcer and other painful diseases of the mouth, oesophagus and stomach. It is said to be useful to reduce the sensibility of the mucous membrane of the nose, ear and larynx and to produce local anesthetics. Parmele Pharmaceutical Co., New York (Jour. A. M. A., Jan. 6, 1912, p. 33).

Lactamoule is a pure culture of *Bacillus bulgaricus*, 12 Ce. in each ampoule. Designed to afford a pure culture of the Bulgarian bacilli for the inoculation of milk or other culture medium, or for direct application in the treatment of affections of the body cavities. Fairchild Bros. & Foster, New York.—(Jour. A. M. A., Jan. 6, 1912, p. 34).

Bacillary Milk is a sterilized fat-free milk fermented by the action of a pure culture of *Bacillus bulgaricus*. It contains over 2 per cent. of lactic acid. It is used as a means for the ingestion of the Bulgarian bacilli and for its lactic acid as well as for its nutritive value. Fairchild Bros. & Foster, New York.—(Jour. A. M. A., Jan. 6, 1912, p. 34).

Destri-Maltose, Mead's contains approximately: maltose 52.0 per cent., dextrin 51.7 per cent., sodium chloride 2.0 per cent., and moisture 4.3 per cent. It is a pale yellowish-white, granular,

odorless powder, sweetish and soluble in water. Maltose being claimed to be more readily assimilable than other forms of sugar, Mead's Destri-Maltose is proposed to supplement the carbohydrate deficiency of cow's milk. Used in milk mixtures in place of milk sugar. Mead, Johnson & Co., Jersey City, N. J.—(Jour. A. M. A., Jan. 6, 1912, p. 34).

Lactic Bacillary Tablets—Fairchild, are made from a practically pure culture of the *Bacillus bulgaricus*. They are designed for internal administration in the treatment of intestinal fermentative diseases by the Bulgarian bacilli, with the design of accomplishing the acclimation of the bacilli in the alimentary tract, so as to secure their characteristic action against putrefactive fermentation by the production of lactic acid. One or two tablets before or after meals. The diet should not contain an excess of proteid, but should afford sufficient sugar. Fairchild Bros. & Foster, New York.—(Jour. A. M. A., Jan. 20, 1912, p. 191).

Salvarsan (Arsenphenol-amin hydrochloride, arseno-benzol, "606") is a 3-diamino-4-dihydroxy-1-arseno-benzene hydrochloride, $HCl.NH_2.OH.C_6H_3As:As.C_6H_3.OH.NH_2.HCl-2H_2O$, corresponding to 31.57 per cent. arsenic (As). It is marketed in hermetically sealed tubes each containing 0.6 Gm. (10 grains) Salvarsan. Salvarsan is a yellow crystalline, hygroscopic powder, very unstable in air. It is readily soluble in water, yielding a solution with an acid reaction. The addition of sodium hydroxide solution to an aqueous solution of salvarsan precipitates the free base ($NH_2.OH.C_6H_3As:As.C_6H_3.OH.NH_2$) which redissolves when more alkali is added.

It is given to adults in doses of 0.3 to 0.6 Gm. (5 to 10 grains) for children the dose is from 0.2 to 0.3 Gm. (3 to 5 grains). In infants doses of from 0.02 to 0.1 Gm. (1-3 to 1-2 grains) may be used. For a subcutaneous and intramuscular injection a suspension in a neutral fluid is commonly employed. This suspension is prepared as follows: The weighed amount of salvarsan is triturated with 0.35 Cc. normal sodium hydroxide solution to each 0.1 Gm. salvarsan. To this liquid a solution of 0.1 Cc. of normal sodium hydroxide solution for each 0.1 Gm. of salvarsan in 8 Cc. of sterile water is added drop by drop until the liquid is exactly neutral to litmus paper. If the neutral point is passed the excess of alkali must be carefully neutralized by a weak solution of hydrochloric or acetic acid. Subsequently, salvarsan may also be administered in form of oily suspensions.

These suspensions should be injected at once, using a syringe with a very thick platinum needle.

For intravenous injection a clear alkaline solution is prepared as follows: The weighed quantity of salvarsan is triturated with 0.7 Cc. normal

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

sodium hydroxide solution for each 0.1 Gm. of salvarsan and then more of the alkaline solution is cautiously added until complete solution occurs.

This solution is diluted with from 100 to 250 cc. (3 to 8 ounces) of sterile physiologic salt solution (0.9 per cent.) and filtered through a sterile filter.

The contents of a tube should be used at once after opening and under no circumstances should the contents of a tube damaged in transportation or any remnants of the powder from previously opened tubes be used. Victor Koechl & Co.—(*Jour. A. M. A.*, Jan. 20, 1912, p. 191).

Proprietaries—Fraudulent and otherwise. An editorial in the *Journal A. M. A.*, discusses the distinction between nostrums and the articles accepted by the Council on Pharmacy and Chemistry. The latter have been found to have some presumable value and to be truthfully advertised. Most proprietaries not accepted have been found to be either fraudulent, worthless or exploited under false claims.—(*Jour. A. M. A.*, Dec. 23, 1911, p. 2087).

The National League for Medical Freedom. An editorial on the National League for Medical Freedom, which opposes public health measures, gives an insight into the aims and motives of those most prominent in the league.—(*Jour. A. M. A.*, Dec. 23, 1911, p. 2091).

Nostrums Exposed in North Dakota. Professor Ladd reports on the composition of the following nostrums and condemns them: Toris Compound, Dr. Green's Improved Compound or Sarsaparilla, Pape's Cold Compound, Caloclide Compound, Eilert's Extract of Tar and Wild Cherry and Red Raven.—(*Jour. A. M. A.*, Dec. 23, 1911, p. 2097).

Radium Teas, one of the latest Paris fads (or fakes) appears to be the exposure to radium emanation while drinking tea or playing whist.—(*Jour. A. M. A.*, Dec. 23, 1911, p. 2098).

Oxidaze Tablets. While formerly exploited to the medical profession, oxidaze is now advertised to the public as a "consumption cure." An examination in the A. M. A. Chemical Laboratory of the stuff as it is now sold, shows the tablets to consist essentially of sugar containing a small amount of volatile oils, starch and a trace of potassium iodide.—(*Jour. A. M. A.*, Dec. 30, 1911, p. 2154).

Natural vs. Synthetic Sodium Salicylate. The Council on Pharmacy and Chemistry proposes to make a thorough study, chemical, pharmacologic and clinical, regarding the asserted difference in action of "natural" and "synthetic" sodium salicylate. The present contribution is a general

discussion by Torald Solman, and a pharmacologic study by J. A. Waddell. Solman outlines the claims of superiority made for the "natural" kind and shows that the evidence is most meagre and not applicable to the product now available. The pharmacologic experiments made on rats, cats and rabbits show no difference in action between the "natural" and "synthetic."—(*Archives of Internal Medicine*, Dec. 15, 1911, p. 784).

Prescription Nonsense. Many competent physicians write poor prescriptions. These often are widely quoted and adopted though most unscientific, worthless or foolish. We are warned that it is the educated physician who is driving the laity to seek drugless treatments to their frequently serious detriment and often hopeless neglect, because he will not endeavor to find a simple drug, administered in a pleasant manner that will help the patient's troublesome symptom without injuring some other part of him. Also, as the layman hates more and more to be "drugged," as he terms it, and dislikes multiple mixtures, and dislikes to pay for a large bottle of some proprietary mixture, he often neglects to seek scientific advice.—(*Jour. A. M. A.*, Jan. 6, 1912, p. 34).

The Conspiracy of Silence. Many lay publications have contracted to publish nothing detrimental to their advertising patrons. While so-called "independent" medical journals do not sign such contracts their failure to acquaint their readers with medical frauds amounts to the same thing. While certain important facts regarding Pepto-Mangan, Anasarcin, Tyree's Antiseptic Powder, Campho-Phenique, Phenalgin, Papine and Antikamnia have been published, "independent" medical journals have, in general, given no publicity to such reports. It is suggested that the "conspiracy of silence" will be maintained so long as an easy-going medical profession will support journals run in the interest of their advertisers.—(*Jour. A. M. A.*, Jan. 6, 1912, p. 36).

"Surgery, Gynecology and Obstetrics" to be clean from cover to cover. Recognizing the impossibility of any one man being able to determine whether or not certain proprietaries are worthy or unworthy additions to therapeutics the managing editor of *Surgery, Gynecology and Obstetrics*, Franklin H. Martin, announces that after Jan. 1st, this high-class journal will carry advertisements only for those proprietary medicines which have been approved by the Council on Pharmacy and Chemistry.—(*Jour. A. M. A.*, Jan. 6, 1912, p. 51).

Convictions Under the Food and Drugs Act. Sweet's Honey Vermifuge. This nostrum was found to contain santonin and senna as its essential constituents. It was declared misbranded because no honey could be found in it and also be-

cause the false claim of harmlessness had been made.

Dr. Town's Epilepsy Cure. This "epilepsy cure" from Fon du Lac, Wis., was declared misbranded because of the ridiculously false claim that it would "cure" epilepsy. Dr. Towns pleaded guilty before the Supreme Court had decided that lies such as he printed were not contrary to the spirit of the Food and Drugs Act.

Dixie Fever and Pain Powder. Headache powders sold by Morris-Morton Drug Co., Fort Smith, Ark. Because of promiscuous, absurd and dangerous claims made for this nostrum it was declared misbranded.

Stello's Asthma Cure. Claimed to be purely vegetable was found to contain: potassium iodid, glycerin, cannabis indica and alcohol. It was declared misbranded because the quantities and proportions of cannabis indica and of alcohol were not stated on the label.—(Jour. A. M. A., Jan. 6, 1912, p. 51).

Society of Universal Science. This was a pseudo-medical cult giving mail-order courses in the "Laws of Human Electricity." It sold mail-order courses that purported to teach the "Laws of Human Electricity and Their Application to Health, Mind, Power and Spiritual Growth." The president of this so-called society was one Andrew McConnell.

Among the responsible men who were duped into endorsing this fake was the Rev. Dr. Robert S. MacArthur, who stands high in the religious world and who on July 7, 1908, at Carnegie Hall, in New York City, is reported to have introduced Andrew McConnell in most glowing terms as the founder of a new method of healing. Probably because of Rev. MacArthur's support many well-known citizens of New York City were present in the audience.

Recently McConnell surrendered to the police. Under the alleged impulse of delusions that she was interfering with his great "work" he had shot at his wife twice. McConnell appears to be an irresponsible paranoiac it may be asked to what extent Rev. Dr. Robert MacArthur and those other "intellectuals" who listened so gravely to McConnell's idiotic vapors were fostering the megalomania which has resulted in a homicidal frenzy of well-nigh fatal consequences.—(Jour. A. M. A., Jan. 13, 1912, p. 129).

"Thyroidectomized Milk." Many attempts have been made in recent years to alleviate the symptoms of hyperthyroidism by the administration of the milk, serum or dried blood of animals deprived of the thyroid gland. The theory underlying these attempts was that, after removal from an animal of the thyroid, toxic substances accumulate in the blood, or antibodies are formed, some of which pass into the milk, and which in some way neutralize the excess of thyroid secretion which is believed to be present in the

blood in hyperthyroidism. The reports from the use of such preparations have not been very uniform. Perhaps the most favorable results reported followed the use of comparatively large amounts (a pint to two quarts daily) of the fresh milk of thyroidless goats.

Dr. Reid Hunt, has suggested that it was the milk per se rather than the presence in it of antibodies which was responsible for the improvement noted. Recent work suggests that Hunt's explanation may be correct. Further clinical observations on this subject are much to be desired.—(Jour. A. M. A., Jan. 20, 1912, p. 197).

Applying the Penalty. A law that provides no penalties for its violation is worthless; in fact, it is worse than worthless, for not only is the law itself inefficacious, but the impunity with which it may be violated creates disrespect for all law. The various pure food laws of the country have accomplished good because drug adulterators and food sophisticators have found it either inconvenient or expensive to violate them. On the other hand the efforts of the Council on Pharmacy and Chemistry to protect the medical profession against frauds and misrepresentations in proprietary medicines are rendered largely abortive because the Council is purely an advisory body and its findings do not result in the penalizing of the concern found guilty of fraud or misrepresentation. The work of the Council would become more effective if physicians would confine their proprietary prescribing to such preparations as had been admitted to New and Nonofficial Remedies and if they would demand that publishers of medical journals, to which they subscribe, purge their advertising pages of products shown by the Council to be worthless, fraudulent, or both. The work of the Council would be effective only if it receives the full support of the medical profession.—(Jour. A. M. A., Jan. 20, 1912, p. 198).

Medical Journals and Nostrum Exploitation. The 250 or 300 independent medical journals published in the United States may be broadly divided into two classes: first, those whose subscription price is sufficient to warrant physicians to expect them to run in the interest of the profession, and second, those whose subscription price is merely nominal and whose real support comes from the advertisers rather than from the subscribers. The term "independent" as applied to medical journals of the latter class, is misleading. Such journals, it is true, are independent of the medical profession, but they are subserviently dependent on the manufacturers of proprietary remedies whose advertising appropriations support them. While the journals of the first class could give the profession a square deal those of the second class can not, for they are dependent on their advertising patrons.—(Jour. A. M. A., Jan. 20, 1912, p. 198).

Exposure of "Patent Medicines". The interest and cooperation which the educational campaign of the American Medical Association is receiving is shown by the following taken from the Albuquerque Morning Herald: "The public-spirited gentlemen who are now posting standard works endorsed by the American Medical Association in various public places in Albuquerque, to enlighten the credulous public on the nature of the various 'cures' and nostrums now in vogue, deserve the gratitude of the people. This is an educational crusade almost as important as the other one started here to teach the boys and girls about the prevention of tuberculosis. 'The Great American Fraud' as Mr. Adams has so aptly termed it, will soon be able to see its finish and thousands of dollars now being donated by the gullible ailing to cold-blooded sharps who play on their apprehensions will be spent to better purpose. War on the fake dopes is war in the interest of the stomachs, health and lives of our people and such a crusade deserves the support of every one. At least it is worth the public's while to read these little books now being distributed about the city."—(Jour. A. M. A., Jan. 20, 1912, p. 200).

Which Will Be Next? With the January issue, **Surgery, Gynecology and Obstetrics** advertises no pharmaceutical preparation that has not been approved by the Council on Pharmacy and Chemistry. Three independent journals now support the Council in this way, namely, **Surgery Gynecology and Obstetrics**, **Southern Medical Journal** and the **Cleveland Medical Journal**. Which will be next?—(Jour. A. M. A., Jan. 20, 1912, p. 200).

Publications Deriving Revenue by Promotion of Fakery. Those publications who derive their revenue principally from the promotion of fakery use various tactics to discredit those forces engaged in exposing worthless or fraudulent nostrums. In an editorial the Druggists Circular, a consistent champion of honest pharmacy, notes that while many journals believe it wiser to say nothing in the hope that the storm will blow over, others can not keep their equanimity and attempt in various ways to defend the nostrum promoters. Readers, generally, however, have grown much wiser regarding many things than they were a few years ago, and as just intimated, are becoming more and more able to discern the whereabouts and the nature of the Ethiopian in the nostrum woodpile. The number of people that may be fooled all the time is continually growing smaller.—(Druggists Circular, Jan. 1912, p. 4).

The J. B. L. Cascade Treatment. The J. B. L. ("Joy-Beauty-Life") Cascade is a device sold by one Chas. A. Tyrrell, an eclectic physician of New York City, for the administration of rectal

enemas. Tyrrell has improved—commercially—on the propaganda started many years ago by Wilford Hall who declared that all the ills of the flesh are due to the fact that people do not make a practice of flushing their colons. Tyrrell sells the appliance for giving these injections and claims that apoplexy, consumption, Bright's disease, syphilis and cancers "all have their origin in the colon" and that "typhoid fever and appendicitis may positively be cured and absolutely prevented by the 'J. B. L. Cascade' treatment." Tyrrell's treatment, which is said to cure everything, consists of his syring and stick of soap and his "celebrated 'J. B. L. Antiseptic Tonic.'" He also sells the "Ideal Sight Restorer" claimed to cure the refractive errors of the eye—near-sight, farsight, old-sight and astigmatism—and also cataract, glaucoma, cross-eye and paralytic blindness.—(Jour. A. M. A., Jan. 20, 1912, p. 213).

Mercolized Wax. "Mecolized Wax" belongs to the "prescription fake" type of nostrum. It is advertised "to remove the thin veil of dead cuticle and leave the skin dry, clear and beautiful." Analysis showed it to be an ointment containing 10 per cent. of zinc oxid and 10 per cent. ammoniated mercury.—(Jour. A. M. A., Jan. 20, 1912, p. 218).

Limitations of Organotherapeutics. The glands of internal secretion are assuming more and more importance in medicine. Attention is now being especially directed to the milder forms of hypo and hyperactivity of these glands.

While organs of animals have been used in medicine for a long time we are but beginning to learn the conditions in which organotherapeutics promises to be of value. In discussing recent advances the Journal A. M. A., says: "The ability to do this in a few cases is due to recent experimental and accurate clinical work, for it is a striking fact that although organotherapeutics is one of the oldest and most wide-spread forms of therapy, not a single result of value was obtained until empiricism was replaced by rationalism." From recorded observations it would seem, a priori, that cases of thyroid deficiency would offer a more promising field for organotherapeutics than would cases of parathyroid and suprarenal deficiency, and these in turn than cases of pancreas deficiency.

It is probable that "not many of the 250 or more preparations of organs of animals found on the market are creditable to modern medicine or to the manufacturers exploiting them. The lists of commercial preparations include such substances as liver, kidney, brain, spinal cord and salivary glands—organs for which there is no, or but very slight, evidence, that they form specific internal secretions—and various preparations of the "internal secretion" of the pancreas, although there is evidence that none of this secretion is retained, at least in an active form,

in this gland."—(JOUR. A. M. A., Jan. 27, 1912, p. 278).

Phenalglin. Phenalglin is a synthetic coal-tar product"—this claim was made some years ago when the profession took the manufacturer's claims at their face value. Then the Council on Pharmacy and Chemistry came into existence and in a report stated that Phenalglin consisted of acetanilid 57 parts, sodium bicarbonate 29 parts and ammonium carbonate 10 parts. To offset the report of the Council the manufacturers, the Etna Chemical Company, adopted the slogan "Phenalglin is just what we have always said it to be."

While the Food and Drugs Act required abandonment of the former claim that Phenalglin was a synthetic and an acknowledgement on the label that it contains acetanilid as its chief constituent, while the firm found it expedient to omit certain other claims from the label, in a general way the same claims are made for the product now that were made formerly. That is, although the Food and Drugs act has forced a certain degree of truthfulness on the Phenalglin labels, the advertising matter is as fraudulent and as untruthful as ever it was.

On the cartons in which the bottles of Phenalglin came, it is stated that the product is "for dispensing purposes only." Yet, as a matter of fact, practically any layman can go to any drug store and obtain this product, otherwise it would not be necessary to include with every bottle a circular naming the diseases for which this acetanilid mixture is supposed to be good and to have the name of the product and of the firm making it blown into the bottle.—(JOUR. A. M. A., Jan. 27, 1912, p. 293).

Fraudulent Proprietaries. What is a fraudulent proprietary medicine? A fraudulent medicine is one that is exploited under false assertions regarding either its composition, its therapeutic effects or both. Formerly false formulas were circulated with utter abandon and no therapeutic claim appeared too absurd. The exposures of the Council on Pharmacy and Chemistry and the enforcement of the Food and Drugs Act have made the declaration of false formulas a risky procedure and hence they have been abandoned altogether or are so worded as to be meaningless. As regards therapeutic claims there has been a slight tendency to abandon the "lie direct" for the "lie with circumstance," but in general the claims are well-nigh as fraudulent today as they were ten years ago. Phenalglin illustrates the type of proprietary humbug that is foisted on the medical profession under claims that are both false and vicious.—(JOUR. A. M. A., Jan. 27, 1912, p. 280).

A Marvelous Mixture. Take acetanilid 57 parts, of sodium bicarbonate 29 parts, of ammonium carbonate 10 parts and mix. You will

then have an "ammoniated coal-tar product" which is such a "judicious combination of ingredients" that it may be counted on "to secure maximum anodyne and analgesic effect." This is "Phenalglin" and, while containing more than 50 per cent. acetanilid, yet its exploiters claim that it has "no depressing effect," "is never followed by depression" and "its prolonged administration does not give rise to destructive blood metamorphosis." These and similar false statements are made in this year of miracles, 1912, and a large proportion of a presumably scientific profession "fall for it" and a multitude of medical editors stand sponsor for it.—(JOUR. A. M. A., Jan. 27, 1912, p. 280).

The Journal of the American Pharmaceutical Association. With the object of furnishing a more direct and speedy means of communication between the American Pharmaceutical Association and its members, the association has established a monthly journal which is to be its official organ. The first number has just appeared. Like the "independent" medical journals drug journals, in general, have found it expedient to withhold publicity of the Association's propaganda for honest medicines. This journal, it is expected, will be the third drug journal that will help the propaganda.—(JOUR. A. M. A. Jan. 27, 1912, p. 282).

Blight and NaturAID Fake. In discussing the personnel of the National League for Medical Freedom the connection of Reynold E. Blight of Los Angeles, Cal., with the NaturAID Health Utilities Company was referred to. The reference was based on circulars sent broadcast by the NaturAID concern. From protests sent by Mr. Blight denying his connection with the concern it appears that, although living in the town in which this quack concern is located, he remained in ignorance of the misuse of his name until it was called to his attention by a journal published in the interest of a profession with which he is not connected and issued 2,000 miles from where he lives.—(JOUR. A. M. A., Jan. 27, 1912, p. 294).

Ayer's Cherry Pectoral. In pointing out that "The Conspiracy of Silence," which formerly reigned over patent medicines now dominated proprietary nostrums, it was suggested that a death due to Ayer's Cherry Pectoral would not have been noted in newspapers. The J. C. Ayer Company objected to this statement because their "Cherry Pectoral of today—"contains no anodyne whatever." The incident calls attention to the variability of composition of proprietaries, whether of the "patent medicine" or the "ethical" kind. Previous to 1905, Ayer's Cherry Pectoral contained morphine and alcohol. The firm having decided to publish its formula the composition was changed. Terpin hydrate was added.

some of the drugs previously used were omitted and heroin was substituted for morphin. The alcohol was retained. Later the formula was again revised and the alcohol left out. Still later the formula was re-re-revised and the heroin left out. Formulas may come and formulas may go, but a nostrum goes on forever—or at least so long as the newspapers will carry its advertisements! If the composition of a "patent medicine" which is sold under an open formula should undergo such radical changes in a comparatively short time, what is happening in the case of those products whose composition has never been made public and whose manufacturers make no pretense of "playing fair" with the public?—(Jour. A. M. A., Jan. 27, 1912, p. 294).

Formanint. Formanint Tablets are widely advertised and extravagantly exploited to the laity in Great Britain. The preparation is put out by the same concern that exploits Sanatogen. The medical profession of this country is now being circularized and advertisements are appearing in medical journals. They already appear in the Medical Record, New York Medical Journal and American Journal of Clinical Medicine. As soon as American physicians have furnished the requisite number of testimonials and have recommended it to sufficient number of their patients the advertisements will no doubt be quietly dropped from the American medical journals and the advertising pages of newspapers and magazines will be called into service.—(Jour. A. M. A., Jan. 27, 1912, p. 295.)

OFFICIAL ANNOUNCEMENTS

DEPOTS FOR BACTERIOLOGICAL MAILING CASES.

The Bureau of Bacteriology has opened depots in every county in the State and mailing cases for bacteriological specimens can now be obtained without delay. Routine examinations will be made free of charge for tuberculosis, Widal and Diazo reaction for Typhoid Fever, Diphtheria, Malaria, Spirochaeta Pallida, Gonococci, Hookworm and all kinds of intestinal parasites. No examination will be now made unless sent in the official containers as it is a violation of the United States Statutes to mail specimens except in especially protected mailing cases. If for any reason the desired containers cannot be obtained at the depots, they will be sent on request, express prepaid.

Containers can now be obtained at the following depots:

Adair—Paull Drug Company, Columbia.
 Allen—Carpenier-Dent Drug Company, Scottsville.
 Anderson—Dr. J. W. Gilbert, Lawrenceburg.
 Ballard—R. R. Roseco, Wickliffe; J. B. Rogers,

Barlow; Dr. John R. Baker, La Center.
 Barren—Leech & Ellis, Glasgow.
 Bath—Dr. A. W. Walden, Owingsville.
 Bell—Dr. J. G. Foley, Pineville; W. H. Sprague, Midlesboro; Dr. B. E. Ginaninni, Straight Creek.
 Boone—Dr. F. L. Peddicord, Burlington.
 Bourbon—Clark & Company, Paris.
 Boyd—Dr. J. W. Kineaid, Catlettsburg; Dr. C. K. Kercheval, Ashland.
 Boyle—J. S. Well's Drug Store, Danville; C. H. Wallin, Brooksville.
 Breathitt—Jackson Drug Company, Jackson.
 Breckinridge—Kincheloe's Pharmacy, Hardinsburg.
 Bullitt—S. H. Ridgway, Shepherdsville.
 Butler—W. T. Kittinger, Morgantown.
 Caldwell—Dr. R. W. Ogilvie, Princeton.
 Calloway—H. P. Wear's Drug Store, Murray; Dr. E. B. Houston, Hazel.
 Campbell—T. D. Widrig, Newport; Dr. C. W. Shaw, Alexandria.
 Carlisle—J. S. Petrie & Son, Bardwell; H. A. Gilliam, Milburn.
 Carroll—W. L. Gaines, Carrollton.
 Carter—Dr. J. W. Strother, Grayson.
 Casey—Dr. I. S. Wesley, Liberty.
 Christian—L. L. Elgin, Druggist, Hopkinsville.
 Clark—J. L. Anderson, Manchester.
 Clinton—Dr. J. A. Sloan, Albany.
 Crittenden—Dr. T. A. Frazer, Marion.
 Cumberland—Alexander-Smith Drug Company, Burksville.
 Daviess—W. E. Danhauser, 404 Frederic St., Owensboro; R. E. Knox, Whitesville.
 Edmonson—J. H. Wood, Brownsville.
 Elliott—Doctors in County supplied.
 Estill—Dr. G. A. Embry, Irvine.
 Fayette—Barnes & Hall, Main and Mill Sts., Lexington.
 Fleming—Aitken & Wilson, Flemingsburg.
 Floyd—Dr. W. W. Richmond, Prestonburg.
 Franklin—J. G. South; H. S. Keller.
 Fulton—Dr. Hugh E. Prather, Hickman; Dr. J. M. Alexander, Fulton.
 Gallatin—B. K. Bailey, Warsaw.
 Garrard—R. E. McRoberts' Son, Lancaster.
 Grant—Harrison Drug Company, Williamstown.
 Graves—B. S. Hunt's Drug Store, Mayfield.
 Grayson—Dr. C. L. Sherman, Millwood.
 Green—
 Greenup—
 Hancock—
 Hardin—Showers & Hay's Drug Store, Elizabethtown; Cecelian Drug Company, Cecelian.
 Harlan—
 Harrison—Dr. M. M. McDowell, Cynthiana.
 Hart—J. D. King & Son, Munfordsville.
 Henderson—Baldauf's Drug Store, Henderson; W. A. Quinn, Henderson.
 Henry—Lester E. Ellis, New Castle.
 Hickman—J. R. Lee, Columbus; J. R. Scarborough, Clinton.

Hopkins—Dr. A. O. Sisk, Earlington; Dr. J. D. Sory, Madisonville.
 Jackson—Dr. W. B. Hornsby, McKee.
 Jefferson—
 Jessamine—Dan P. Hemphill, Nicholasville; Dr. H. L. McLean, Wilmore.
 Johnson—Dr. G. V. Daniels, Paintsville.
 Kenton—
 Knott—
 Knox—Dr. J. S. Locke, Barbourville.
 Larue—Ferrill's Drug Store, Buffalo.
 Laurel—W. H. Paynter's Drug Store, London.
 Lawrence—Dr. J. J. Gambill, Blaine; Dr. A. W. Bromley, Louisa.
 Lee—Dr. C. B. Cann, Beattyville; Dr. L. F. Gibson, Heidelberg.
 Leslie—Ray Brothers, Druggists, Hyden.
 Letcher—
 Lewis—Dr. L. A. Grimes, Concord; Dr. J. F. Irvine, Tolesboro; Dr. J. M. Wells, Vanceburg.
 Lincoln—Drs. Brown & Phillips, Stanford; W. J. Childress, Houstonville.
 Livingston—N. R. Farris & Co., Salem; Dr. F. G. Larue, Smithland.
 Logan—J. M. Perry, Druggist, Russellville.
 Lyon—Dr. J. H. Hussey, Eddyville.
 McCracken—
 McLean—W. H. Howden, Druggist, Calhoun.
 Madison—Joe Schafhausen, Druggist, Richmond.
 Magoffin—Kash Drug Store, Salyersville.
 Marion—Dr. C. B. Kobert, Lebanon.
 Marshall—Dr. V. A. Stilley, Benton.
 Martin—
 Mason—
 Meade—Dr. J. R. Dink, Brandenburg.
 Menifee—
 Mercer—C. M. Dedman & Son, Harrodsburg.
 Metcalfe—Briggs Drug Store, Edmonton.
 Monroe—
 Montgomery—Thomas Kennedy, Druggist, Mt. Sterling.
 Morgan—B. F. Carter, West Liberty.
 Muhlenburg—Dr. E. R. Yost, Greenville; Dr. J. T. Woodburn, Central City.
 Nelson—J. M. Wilson, Druggist, Bardstown; J. S. Rodman, New Haven; C. P. Brown, Bloomfield.
 Nicholas—Dr. Malcolm Dills, Carlisle.
 Ohio—Herbert Sanders, Druggist, Hartford; J. Dr. Cooper, Druggist, Fordville.
 Oldham—McDowell & Son, druggists, La Grange.
 Owen—Dr. C. F. Alexander, Gratz.
 Owsley—Dr. A. M. Glass, Booneville.
 Perry—Kelley-Engle Drug Company, Hazard.
 Pike—Dr. Z. A. Thompson, Pikeville.
 Powell—J. W. Johnson, Stanton.
 Pulaski—Dr. A. W. Cain, Somerset.
 Robertson—Dr. W. S. Chandler, Mt. Olivet.
 Rockcastle—
 Rowan—Dr. A. Scaggs, Morehead.
 Russell—G. F. Jones, Druggist, Jamestown.
 Scott—Thompson & Con, Georgetown.

Shelby—Dr. S. L. Beard, Shelbyville.
 Simpson—Dr. M. M. Moss, Franklin.
 Spence—W. T. Froman, Taylorsville.
 Taylor—R. L. Hill, Druggist, Campbellsville.
 Todd—
 Trigg—
 Trimble—T. R. Ingalls, Druggist, Milton.
 Union—Dr. S. L. Henry, Morganfield.
 Warren—Ewing's Drug Store, Smith's Grove.
 Washington—Hayden & Willett, Druggists, Springfield.
 Wayne—Dr. J. F. Young, Monticello.
 Webster—Dr. J. A. Goodson, Dixon; Dr. C. L. Edwards, Sebree.
 Whitley—The Smith Drug Store, Corbin; E. W. Nelson Drug Company, Williamsburg.
 Wolfe—Dr. B. D. Cox, Campton; Dr. A. C. Nicholls, Hazel Green; Dr. G. M. Center, Toller; Dr. S. S. Swango, Valeria.
 Woodford—B. B. Smith & Son, Druggists, Versailles.

ANTITOXIN DEPOTS.

Jackson—Dr. G. C. Goodman, Welchburg.
 Christian—Elgin's Drug Store, Hopkinsville.
 Marshall—W. T. Little, Calvert City.
 Graves—H. H. Hunt, Mayfield.
 Carroll—P. V. Ellis, Ghent.
 Marion—R. C. McChord, Lebanon.

To the Editor:

I enclose copy of letter sent this day to the Louisville Evening Post. Doubtless it will be thrown into the waste basket by them. If a few hundred medical men and their friends were to write such a letter and mail to the Post or other offending papers, they would begin to sit up and take notice.

Yours truly,

I. S. MANNING.

Manchester, Ky., Feb. 8, 1912.—Editor, Evening Post, Louisville, Kentucky.—Gentlemen: I have been a subscriber for the Evening Post for years, my annual subscription is about to expire. I am debating in my mind whether to renew my subscription or quit. Many things I find in the Post that I can commend. The Post's ideas of reform and progressive politics meet with my hearty approval; then too, as a general thing, its position is sound on morals, temperance, education, business, law and order.

I take exception to a practice the Post has of making scare headlines and pseudo-scientific introductions to D's pills, P's sawbrier juice, and X's soul-tablets. An unsophisticated reader often fails to find the *res gestae* until he has absorbed the slop on the surface. The readers mind thus water-logged with poison has lost its discriminating power. The suggestion of the artful advertiser has already brought out each symptom as fast as describ-

ed. The reader can see only one relief, buy the nostrum and be healed.

A further complaint I make: I do not want to have Charley Moonshine's disgusting mug and his fraudulent claims thrust in my face 300 and odd times a year. Too much of the Post's space is given up to patent medicine swindles and swindlers.

The Post's rake-off from this class of business is blood-money, taken from poor, sick, discouraged, and dying wretches; just how much it gets and how much the other fellow gets is immaterial. In equity its* should be much the larger share because it creates the sole market for his class of warts by publishing the lying, fraudulent advertisement. Drop the advertisements and this business would cease forthwith.

Now, as to my part, I would willingly pay twice the subscription rates for a clean, live newspaper that I could introduce into my home without any compulsions of conscience. I just send you this in the hope that you may clean up your paper.

Yours very truly,

*Post's.

Laparotomy for Placenta Previa.—In the first two of the three cases reported the patients were elderly primiparae and after considerable hemorrhage the child was removed by Cesarean section and both mothers and children were dismissed in good condition, with nothing to interfere with future pregnancies. The third patient was a woman of 40 at term with her eighth pregnancy, faint from excessive losses of blood, the fetus dead. The abdomen was opened and the uterine arteries ligated and ligaments tied off. The pulse began to improve at once, and supravaginal amputation of the unopened uterus was rapidly done and the patient was replaced in a warm bed, the pelvis raised.

Infusion Anesthesia.—The most striking features of infusion anesthesia, Rood says, are: Extreme flexibility so that the condition of the patient can be adjusted with great nicety and can be changed in the direction of deepening or lightening the anesthesia with really remarkable rapidity. That the patient begins to come round very soon after the anesthetic is stopped and is able to converse rationally within a few minutes. That postanesthetic vomiting and pulmonary irritation are both extremely rare. Rood has used it with much satisfaction in twenty-one cases.

ORIGINAL ARTICLES

ACUTE SPINAL PARALYSIS; DIAGNOSIS AND TREATMENT.*

By JOHN J. MOREN, Louisville.

In older text books we were taught that, "Anterior Poliomyelitis," commonly called infantile paralysis, was a motor paralysis, generally monoplegic, of the muscles that are associated in function, followed by atrophy and electrical alteration in these muscles. Cerebral, sensory, rectal and vesical symptoms being absent or temporarily in duration." The causes in many cases were unknown, but causative factors as age, season, infections, exposure to cold, trauma, strains, etc., were mentioned. The disease was known to be located in the anterior cornua of the cord. The exact origin of this injury could not be interpreted, some believed it was a parenchymatous degeneration of the cells, some held it to be interstitial in origin, others thought it originated through the vascular system. Small epidemics have been referred to by the early writers, but nothing definite was known of the infectious nature of this disease.

This is not a new disease. Endemic cases have occurred in all the states for years, but a new phase of the disease is the epidemic. The first intimation of an epidemic was reported from Alabama about 1841, but the first actual report was recorded in Europe in 1881. The first reported in America was in Vermont in 1894. Several smaller epidemics occurred along the Atlantic coast. In 1905 Norway had quite an extensive epidemic, and in 1907 the New York epidemic occurred; 1908 seemed to be a quiet year. In 1909 Massachusetts suffered as well as other states, and each year thereafter one or more epidemics have occurred. Altogether about fifty epidemics have been recorded. Four-fifths of the cases in the past four years have occurred in the United States. The majority of these cases have occurred in children, due doubtless to a lessened resistance than adults.

When we stop to think of the thousands of crippled children resulting from these epidemics, it is certainly worth our while to do all we can to break the ravages of this disease. Happily the best investigations and information of this disease have been obtained by the American doctor, he is not asleep and the details of this disease will sooner or later be brought to light. As a result of the investigations of the epidemics which have been carried on the last five or ten years, a distinct change has occurred in the nature and conception of the disease. To-day the

*Read before the Whitley County Medical Society.

lesion is not confined to the anterior cornua of the cord, the cortex, midbrain and meninges suffer. Flexner says that the brunt of the attack is spent on the meninges and that there is a congestion with small hemorrhage in the anterior horn. The explanation of the frequency of the lumbar and cervical portions, as well as the anterior horn, is due to the fact that this portion has a more abundant blood supply.

It is now regarded, pathologically as an acute infiltrative, nonpurulent inflammation, due to some microorganism which has a pre-delection for the nervous system and is carried to the nervous system by the circulation. The organism has not been demonstrated but experimental investigations have furnished us some facts. It is conceded that the nasal tract is the most probable avenue of entrance. An emulsion made from the nasal secretions will produce the disease. Dixon and others have failed to transmit the disease by frequent swabbing of the nasal tract of polio cases, and Landsteiner succeeded in transmitting the disease from the tonsils, nose and pharyngeal secretions. Some believe that infection occurs through the digestive tract, but it seems to be conceded that the nasal is the most important. It is a question whether the saliva, urine and feces carry the microorganism, however it is recommended that they be disinfected. It is known that it is not a very infectious disease, for monkeys suffering from polio in the same cage with healthy monkeys, do not infect others. Also, in the majority of cases occurring in an epidemic only one member of a family is affected. In proportion to the number exposed, very few suffer. How the virus is carried from one person to another is not known, many suggestions have been made but none proven. If it is carried by an insect it is as Flexner says, one that goes with travel.

In view of the fact that it is accepted to be an infectious disease, how about the old list of causes? Age and season must be retained, but dentition, trauma, exposure, etc., can only contribute their portion of making the patient more liable to infection. They do not cause the paralysis.

DIAGNOSIS.

All writers in the past few years use Wickman's classification which is as follows:

- (1) Spinal poliomyelitic form,
- (2) Ascending form,
- (3) The bulbar or pontine form,
- (4) Cerebral or encephalitic form,
- (5) Ataxic form,
- (6) Polyneuritic form,
- (7) Meningitic form,
- (8) Abortive form,
 - a. General infection,
 - b. Meningeal irritation,

- c. Pain, like influenza,
- d. Cases with digestive disturbance.

The point of interest about this classification is the question, how many cases of polio have been treated as other diseases? You will note immediately that epidemic acute spinal paralysis may take special forms and the name polioencephalomyelitis is the better name, as the disease is not limited to the spine, but may affect the brain and even the nerves. You will also note that a disease with such a variety of manifestations is going to cause trouble for the diagnostician.

I am satisfied that the cases of simple poliomyelitis that I have seen in the past two or three years are different to some extent, from those that I saw previously. They are different in the manifestations of sensory symptoms, particularly hyperaesthesia. You will recall cases that after the first day or two practically no pain or sensory symptoms existed. I have had under my observation in the last year cases that have retained hyperaesthesia for months after the original attack. From the cases that I have observed there are some special points about the development of symptoms that will help to distinguish it from other diseases. For instance, the fever usually starts in reasonably high, reaches its height in twenty-four to forty-eight hours and in a week's time drops to, or below, 100. Paralysis occurs within this time, and the fever ends by crisis. Hyperaesthesia often appears with the subsidence of fever. The pulse in the beginning is rapid and out of proportion to the general symptoms except in the meningeal types. In the reported cases note the rapidity of the pulse. I know of no disease with paralytic symptoms with these characteristics so marked, and if kept in mind will enable you to distinguish many cases that otherwise would be a source of great anxiety.

DIFFERENTIAL DIAGNOSIS.

No. 1. The symptoms in this type are as a rule in keeping with the text book pictures which you are familiar with, and within forty-eight hours one should be satisfied as to the nature of the condition to be contended with.

No. 2. Or the ascending form, is usually the one that ends in death. It resembles Landry's paralysis, and raises a question as to whether the latter is another type of polioencephalomyelitis, and not a distinct type of its own. Many writers are of this opinion. It seems that the virus studied by Flexner is more violent in its effect than that of Landsteiner, and these ascending cases may be a more severe poison than those as in No. 1.

No. 3. In this type the paralysis is confined to the cranial nerves or occurs in the same cases that suffer paralytic symptoms of the

extremities. Isolated palsies of the seventh and third nerves from polio are very interesting. I know of a child under four years of age, who had a tonsillectomy, and after convalescence ran a fever and had complete paralysis of the seventh nerve. While the attending physicians regarded it as simple Bell's palsy, the parents were alive to the question, is it polio?

No. 4. There is some doubt about this form. Hemiplegia and spastic paralysis, suggesting brain lesions, have been noted along with well defined cases of polio, but whether they were true cases of polio is not established. Impairment of intellect has been noted in a small per cent. of cases.

No. 5. Manifest ataxia resembling that of Friedrich's ataxia and the lesion is confined to the cerebellum and midbrain.

No. 6. This form has been demonstrated by postmortem findings and resembles simple polyneuritis from other causes, however, in the latter you will note the onset of paralysis extends over a longer period of time, there is more marked loss of sensation, more tenderness along the course of the nerves, more vasomotor signs in the extremities, and usually more frequent in older people: while in polio the onset is sudden, the paralysis will not deepen, and the anaesthesia will not be so marked. One is a nuclear and the other a peripheral nerve disease.

No. 7. Various forms of meningitis have occurred during epidemics of polio. Last year in England an epidemic of cerebro-spinal meningitis followed an epidemic of polio, consequently, the meningeal form of polio will cause a good deal of trouble in distinguishing it from other forms of meningitis. Especially in childhood any irritation of the meninges will be ushered in by headache, vomiting, general restlessness and fretfulness, so in the meningeal types of polio the attacks may be introduced by headache, projectile vomiting, convulsions, etc., as in other types of meningitis. One cannot speak positively until the expiration of two to four days, unless we resort to lumbar puncture. This is the only means that we have at present which is thought to be of real diagnostic value.

It is said that the cerebro-spinal fluid is clear and void of micro-organisms and runs from the needle as if under high pressure. In meningitis of other causes it is floccular and contains diplococci intercellularis, streptococci or tubercle bacilli. However, the lumbar puncture cannot always be practiced, so we must rely upon our clinical signs.

In tubercular meningitis we usually have more premonitory signs, it usually occurs in delicate children, the attack is likely to be less severe and more prolonged without diagnostic paralysis, the pulse is often slow and the

fever curve is likely to vary, increasing with the development of the condition? If local paralysis occurs in tubercular meningitis it is likely to shift, come and go or vary from day to day. The tubercular patient is less sensitive to noise than the polio. In cerebro-spinal meningitis, pulse and temperature are high, rigidity, stiff neck and Kernig's sign are pronounced, while in polio stiffness of the neck may be present in various degrees, but it is said that the child can move the head from side to side. Kernig's sign is likely to be irregular and more marked in one leg than in the other. Difficult swallowing is attributed to pain and not to the rigidity. Again as we referred to above, the temperature reaches its maximum then drops, in other words, the fever lessens with the onset of paralysis. The mental state of polio is liable to be of great value. Delirium and stupor may be pronounced in cerebrospinal, may vary with tubercular, though deepen with the progress of the disease; while in polio it may not be so pronounced, start in with a flurry, clear up quickly or the little trick may appear as if suffering from brain disease and still "look bright."

No. 8. The abortive cases without noticeable paralysis present the greatest confusion. Each epidemic has furnished its portion, the most important diagnostic point is the occurrence of other cases with paralysis. Personally, I have not observed a case, but it seems a very difficult problem to correctly interpret these cases. So often the family physician meets cases in which he feels reasonably certain that there is a toxic condition but to say what toxæmia is present is never known. So you can appreciate the difficulty in these four types of abortive cases.

On account of the frequency of gastrointestinal symptoms in polio, and the frequency of enteritis occurring in the summer, the abortive form with leading digestive disturbances makes one feel uneasy, especially if the patient has been exposed in any way to a polio patient. Judging from the literature one is impressed with this fact. In enteritis the patient suffers more from digestive symptoms and little nervousness, in polio the nervousness is more pronounced than digestive disturbances.

In some epidemics cases have developed rash. From what I can gain from the literature, this may resemble scarlet fever or other infectious diseases. The literature leads one to believe that the rash occurs on the body instead of the face and hands as in exanthematous diseases. Last summer I was called to see a sick child with an obscure febrile history. The erythema was confined principally to the body. The doctor considered polio but it proved to be, as is often the

case in childhood, an irregular typhoid with hives.

As polio is a hot weather disease we must keep in mind the other diseases occurring this season of the year. Last summer I was called to see a little girl of ten years who had a little scratch on the hand, later she developed a marked spastic condition of extremities with only a slight nuchal stiffness, irregular temperature running as high as 102, no delirium or stupor, to the contrary was bright. She was a delicate child. We agreed that it was tubercular meningitis, and so it proved to be. However, tetanus was considered and the family physician at first thought of polio. In epidemics which have occurred cases of tetanus have been considered polio. While they may resemble it in the early stages and particularly in the milder cases, in twenty-four or forty-eight hours your clinical history and symptoms will enable you to distinguish between the two. Rabies, tonsillitis, diphtheria, acute rheumatism, and especially muscular rheumatism, as well as many other diseases with fever, have been mistaken for polio. Children with scurvy and weakness resembling paralysis must be mentioned. Last fall I was asked to see a bottle-fed child, who suffered a partial paralysis of one leg. The family physician considered it polio, the consultant thought it scurvy. The reaction of degeneration to the electric current and loss of reflexus ruled out scurvy.

Hysteria and syphilis need only to be mentioned, as these two conditions must be considered when paralytic symptoms appear. On account of the great variation in types of polio you can readily understand how the various cases may resemble clinical pictures and offer difficulties to the diagnostician.

It is important that we should be familiar with this new form of polio, as epidemics have occurred all around us. Covington, Ky., had a small epidemic last year, and it is not improbable that we may be called upon to battle with a more severe outbreak. I have confidence in the State profession and am sure they will be "on the job."

TREATMENT.

In the management of these cases it is convenient to divide them into three stages. First, that of the immediate attack and extending to the point of disappearance of pain. The duration of this stage may vary. Second, the period from absence of pain to the disappearance of hyperaesthesia. Third, the chronic stage. Unfortunately, no measure or treatment acts as a curative agent. Experiments along the line of serum therapy have been made but no results accomplished, consequently, we have been compelled to treat these cases symptomatically. The administration of urotropin has been tested and found

to be of service in increasing the incubation period several days and doubtless lessened the severity of the attack, but the observers in the various epidemics do not report very favorable results after the patient is once infected. However, I believe it is a good drug, and knowing its harmlessness would advise it. Intestinal antiseptics have been used but of course only influence that specific tract. As for elimination the salicylates are good. A mixture of potassium acet. spt. ether nitr. each dram and one-half; liq. ammon. acet. aqua. camphor, each three ounces, Larabee's fever mixture, has served me satisfactorily in febrile attacks in children. Pain should be controlled by application of heat or administration of anodynes or opiates. Whether counter irritation by irritants or cupping should be used, has been questioned. Can you influence the circulation of the cord by such measures? The arteries to the cord come from the vertebral, a branch of the subclavian and also the aorta which give off the lumbar arteries, and can not be influenced very much by local application to spine, consequently such measures are likely to do no good, and increase the discomfort of the patient.

No harm can come from gentle rubbing but massage should not be used. Some one has suggested the use of the galvanic current to contract the paralyzed muscle to relieve the pain. This procedure seems reasonable and I should use it when the occasion arises, however, we must bear in mind that we should not over-stimulate the peripheral nerve for fear of increasing the damage to the cord.

For the relief of sensitiveness the neutral bath or sponge bath may prove the best. Doubtless this is due to the meningeal irritation and measures directed in relieving congestion and promote elimination are to be preferred. If the fever continues high full baths should be used with caution, if used at all. Such measures act best in the second stage.

In the first stage the doctor should be mindful of future deformities. Proper care in seeing that the paralyzed muscle is not over-stretched by heavy bed clothes or faulty position will materially lessen the manifestations of contractions and deformities.

After the acute stages gentle massage and galvanism can be used. Your medication will vary according to the condition of the patient. If digestive trouble persists, that is the one thing to fight. In the recent epidemic in Idaho constipation existed in over sixty per cent, and often persisted even to the second stage. The amount of exercise permitted at this time is gauged according with the condition. Fatigue is to be avoided, but fresh air is essential to good health.

There is a prevailing opinion that all im-

improvements occur in the first two or three months. This is not correct, improvement has been noticed a number of months after the attack, and we should persist in our treatment and watch the progress of the patient. However, as your patient approaches the third stage you can well judge how much permanent damage has been done. Usually after the second week all muscles that respond to the faradic current will be restored. A better function may be obtained in some that do not respond. The nerve supply does not come from a particular level of the cord, hence the return of motion of apparently permanent paralyzed muscles after the congestion and oedema of cord has subsided and with the improvement in nutrition of the impaired muscle obtained by massage and electricity. In the third stage, the patient has reached a point where medication is of little value other than in the form of general tonics. The best results follow physical measures, massage, resistive movements, electricity, hydrotherapy, vibration, etc. Your aim should be according to Lovett:

1. The prevention of deformities.

2. The regaining of nerve and muscle power.

When and where not to use splints, braces, etc., must be judged according to the degree of paralysis and rapidity of improvement. Let them use their legs to develop muscle power rather than shield it by braces. However, we should not overlook the fact that watchfulness and care might save an ugly deformity. At this time it is well to have the orthopedic surgeon to help advise the policy to be pursued.

To improve the nerves and muscles, I do not believe anything can replace massage, including active and passive movements, and electricity. A trained masseur is to be preferred, but equal results can be accomplished by instructing an intelligent mother. As for the form of current used, the galvanic is best. Some favor the sinusoidal and high frequency, each will stimulate, but for its effect upon the deeper structures and paralyzed muscles, the galvanic can not be replaced by any other form of current.

The unfortunate or pathetic side is the fact that a large number of these patients go to the unscrupulous quacks. It is a shame that our laws are so constructed that such practitioners are permitted to prey upon the imagination of distressed people. The only consolation the honest doctor has is the feeling that he has done his best and that he is a subject to obey the law and not to make laws.

A WORD FOR PROPHYLAXIS.

It is generally accepted that this disease should be reported as other infectious and contagious diseases. The number of cases

occurring in an epidemic is comparatively small, I believe New York had the largest. The mortality is considered about eight per cent. The per cent. of total recoveries is from fifteen to twenty-five. This leaves practically seventy-five per cent. crippled more or less for life. It is estimated that about nine thousand epidemic cases have occurred in the past five or six years. Just think of the cripples? Do you not understand why parents are uneasy about this disease? It is difficult to give suggestions when so little is known about the habitat of the virus. The best policy is to take no risk even of the third person. The child should be isolated for at least three or four weeks after the attack. The organism has been found to exist in the nasal tract five or six months after the attack. A nasal wash of 1 per cent. peroxide of hydrogen, has been found sufficient and effective in destroying the virus. However, we should be careful not to use too strong solutions of any antiseptic for fear that we cause irritation and produce open surfaces. Persons who have abrasions or rather open surfaces, develop the disease quicker than those who have not. A case under my observation has a nasal tract affection and was exposed to a child who had some particular ailment without paralysis. Within twenty-four hours afterwards the child was sick and developed diphtheria. There were two other cases of infantile paralysis in the immediate neighborhood. Whether the nasal affection predisposed an early infection, or whether the sick child had an abortive polio cannot be answered.

The question of "carriers" is very important, but at present is not solved and it remains for the doctor to use care and advise the use of simple naso-pharyngeal antiseptic.

Dixon, of Pennsylvania, has isolated a micro-organism in the blood, but whether this will prove to be a virus of polio remains to be demonstrated, if so it will materially change our views of the disease and methods of prevention.

Injection of Blood Preliminary to Operations.

—Esch refers in particular to extremely anemic and weak patients with hemorrhagic uterine myomas. They need myomectomy at once and yet their resisting powers are at a dangerously low ebb. In order to improve conditions he injected defibrinated blood in two cases; three injections of 20, 15 and 30 c.c. and 15, 20 and 22 c.c. of the defibrinated blood in the course of fourteen days, improving the condition to such an extent that the hysterectomy was then safely performed. The hemoglobin rose from 25 to 46, and from 23 to 36 per cent., the improvement parallel in both cases and evidently strictly connected with the injections.

DIAGNOSIS AND TREATMENT OF
CEREBRO-SPINAL MENINGITIS.*

By J. H. PARKER, Corbin.

Fortunately this is not a disease that we see very often. It exists in the epidemic and sporadic form, and I believe that it was first described in 1805, and since that time it has prevailed in different localities in epidemic and sporadic forms. In the severe types it is usually easily diagnosed, while in the milder types it is more difficult. In the severe types the onset is sudden with severe pain in head and neck with more or less pain in muscles of the body, vomiting with projectile force and chills, the muscles are rigid and pain is increased on motion. There is usually fever for the first two or three days, usually not higher than 102, the pulse is slow the first few days and may go down to 50 or 60. The fever after the third day usually comes and goes and sometimes it will be subnormal. The eyes usually become congested and we will notice purulent secretion in corner of eyes, by the third day. Photophobia which follows immediately the onset of head ache, hyperaesthesia. The child complains if it is touched or moved in bed. The head is inclined to be thrown backwards. It wants to lay on its back often with limbs drawn up. Eyes partially open, taking no notice of anything, ask for nothing, only to be let alone. Bowels are usually constipated, kidney secretion is very much diminished and highly colored. Tongue after the third day is dry and red, mouth partially open. Then many times very restless, crawling all around over the bed and complaining of great pain, and not sleeping any as a rule. We do not have the convulsions with head almost drawn back between the shoulders, only in severe cases, and those that will most surely die. The vomiting usually subsides by the third day, however it may continue through the attack. There is complete loss of appetite.

Now in the milder cases or complicating ones, the symptoms are not marked and we may not be able to make our diagnosis for several days. As it may be complicated with croupous pneumonia and rheumatism, tubercular meningitis is of slower form and is not violent. In the typhoid types it is often very difficult to determine whether we have one or the other disease. I think that when cerebro-spinal meningitis is epidemic in the community we are more likely to call it meningitis whether it is or not. And it may be necessary to draw off some of the spinal fluid and to have a microscopic examination made before the condition can be determined.

Now as to the rash I have never been able

to find it in any of the cases that I have seen. Still all of the authorities speak of it prevailing in a great majority of cases in some form. But I have frequently seen the herpes labialis.

Kernig's sign has not proven to be of any help to me in making the diagnosis, for the children were so irritable about being disturbed that they resisted any molestation in the severe cases, and in the milder cases I do not think it is manifested. I have usually found that towards the end, in the severe cases, they lose control of the bowels and bladder, passing urine and bowels moving unconsciously. They complain of light and noise. I have had about all the cases I have ever seen in spring and early summer. I do not believe that I have ever seen this fact mentioned in any of the authorities, that I have read. And I only mention this that it may be brought out in the discussion, as to what the experience of other doctors has been along this line.

TREATMENT.

That is where we are in trouble again! So far our treatment is both symptomatic and supporting. We should keep our patient in a dark room with perfect quietude, no company should be allowed and patient should not be disturbed any oftener than possible. I think this is the most important part of the treatment, and about the hardest to enforce. The food should be simple and liquid, with plenty of water, or lemonade. We should make an effort to relieve the pain and of late years I have been using 1-4 grain of codeine hypodermically as often as was necessary, and in my absence to take it by the mouth sufficiently often to relieve the pain. They can almost certainly be relieved of pain in this way and be able to sleep and I think codeine disturbs secretion less than any narcotic we can use. Hypodermics are decidedly more effective than any other way and we will soon find that we will have to increase the dose to a half or three-fourths of a grain to meet the requirements. Children will often fuss about the first few doses hypodermically, but will soon permit it to be used without much complaint. I have always given from one to three grains of calomel in twenty-four hours to keep the bowels open, and with some hopes of reducing the congestion and inflammation of the brain and the spinal cord.

The bromides and iodides are so bad to take children will resist them so intensely that if they would accomplish any good I think the disturbance would do more harm than the medicine would do good. I think it is well to shave the head or clip the hair with clippers as closely as possible and to use an ice cap continuously as long as the fever lasts. And after the fever has subsided to use them from time to time. And if the fever should run high, I think the Leiter coil for the body is

*Read before the Whitley County Medical Society.

best. Do not think we should sponge to any extent or use tub baths, as the skin is too sensitive to the sponging. I do not think we should disturb them by putting them in the tub as they seem to be so easily frightened. In this condition the most absolute quiet is one of the most important parts of the treatment. We may use counter-irritants to the nape of the neck; not to blister, as it seems to annoy them and it interferes with application to the head.

Now as to the serum treatment. I have never used it nor seen it used, and I only mention this that it may be discussed.

So far fatalities have been appalling and those in most instances that do get well, were maimed to such an extent that we almost felt that it would have been a blessing to them and their parents if it had resulted fatally. While I have seen a few complete recoveries, I do not think more than 20 per cent. of the severe types recover. I recall an epidemic that I had several years ago of ten cases of the severe types. With six recoveries, three complete and three defective results, consisting of deafness and partial paralysis.

DISEASES OF PROSTATE.*

By S. M. HOPKINS, Demossville.

Our subject includes all the diseases of prostate. As this would make a very lengthy paper we will first briefly consider some of the rarer affections. Prostatitis, inflammation of prostate is rarely a primary disease, but is usually secondary to epididymitis, cystitis, proctitis and especially to specific urethritis, also traumatism externally, or internally by use of instruments. Excessive venery may be a cause. The disease begins with all the characteristics of inflammation, pain, redness, heat and swelling. With finger in rectum the swelling will be observed, also throbbing of the arteries. Fever is present, and urination painful.

The first thing in the treatment is to put patient to bed and open bowels. Put ice-bag to perineum. If retention of urine occurs use soft catheter. If pus forms it should be aspirated or incised through the perineum. The abscess often opens into urethra, or it may open into rectum, or through perineum.

PROSTATORRHOEA.

This is chronic prostatitis, and has about the same causation as the acute. It is sometimes seen in weak, scrofulous or tubercular adults about the time of puberty. The characteristic symptom is bluish-white discharge from meatus. The diagnosis between this and spermatorrhoea is made with microscope.

The treatment is general and local. Give any predisposing diathesis, the proper attention. The passage of steel sounds, and deep injection of ten to twenty grain solution of silver nitrate is the best local treatment.

Carcinoma and sarcoma of prostate may be either primary or secondary. A tumor of prostate in the young or middle-aged is looked upon with suspicion of malignancy. Hemorrhage often follows micturition and is usually profuse after use of catheter. If the disease is recognized before involvement of the lymphatic glands, while the trouble is altogether within the capsule, then the removal of the tumor is indicated, otherwise the treatment is palliative.

PROSTATIC CONCRETIONS.

The symptoms are those of the enlargement and inflammation that the stones produce. The subjective symptom is the interference with urination. The enlargement of gland is made out with finger in rectum. A positive diagnosis is only made by striking stone with a sound. The treatment is surgical.

We now come to the most important disease of prostate, viz:

HYPERTROPHY.

Pneumonia has been spoken of as a friend of the aged. Hypertrophy of prostate it seems might with equal propriety be called the curse of the old man. It is said that one man in every three between the ages of fifty-five and seventy-five has hypertrophy of prostate, and that one man in every nine has a troublesome hypertrophy of prostate. The disease comes on insidiously. The first symptom is increased frequency and decreased power in passing urine. The bladder is unable to completely empty itself, and soon sets up cystitis. With some patients retention of urine is about the first symptom they complain of. The bladder is distended, the contractibility of muscular coats are diminished. Cystitis, pyelitis, renal insufficiency and auto-intoxication are all caused by prostatic hypertrophy. Inability to empty bladder causes back pressure through ureters, and that in turn sets us a renal insufficiency which may cause auto-intoxication. Pyelitis acts in two ways, by its septic poisoning, and its influence on the function of kidneys. Patients who are compelled to use catheter daily often develop a septic infection, so-called catheter fever, supposed to be caused by some abrasion made by catheter, or by use of dirty catheters, but I have on hand a case: Man, aged 78, who has same kind of attacks, chills followed by fever, who has never used catheter, although he has great difficulty in passing urine. In these attacks he passes some blood. His prostate seems to be nearly as large as my fist. The objective symptom in prostatic hypertrophy

*Read before the Pendleton County Medical Society.

is dependent upon a digital examination of rectum. The proper treatment of prostatic obstruction is prostatectomy. In most cases an operation will be refused so we will be compelled to palliate. When the catheter must be used the patient must be instructed how to sterilize and use them. The bowels should be kept open. Alkaline diuretics sometimes renders the urine less irritating. Urotropine is the best urinary antiseptic. In the septic cases irrigation of bladder with boric acid solution often gives relief. Have patient drink plenty of water, which is best of all diuretics. It is well to advise patients to avoid venereal excitement; this advice may not always be heeded. Forchheimer recommends massage of the gland.

Prostatectomy virtually began in 1885, and for several years was performed in a crude way. Most of our surgeries published before 1900 do not even mention the operation, but in the last decade the operation has been so perfected that to-day it almost heads the list of pain relieving and life-saving operations. Like as in the operation of appendectomy, it is here that procrastination gets in its work. Some surgeons prefer the suprapubic and others the perineal route. It is not the purpose of this paper to discuss the route, but to urge an early operation, while the bladder and kidneys are healing.

GONORRHOEA AND SYPHILIS.*

By J. J. RODMAN, Owensboro.

Rev. Charles Coppens, S. J., Professor of Medical Jurisprudence in Craighton Medical College, Omaha, Nebraska, said:

"It is the physician's beneficent task to lessen the weakness and suffering of the body, and to prolong human life in well-preserved vigor to a green old age. It is not the least important part of his valuable services to provide for the sound and vigorous propagation of the human race to future generations. If the purpose of the physician were only to make money, his task would then be to multiply diseases and infirmities; he would then be as great a curse to mankind as he is really intended to be a blessing—and an immense blessing he will be to his fellow men if he studies to remove even the remote causes of diseases and untimely deaths. He can do so in a variety of ways, and not the least by providing against sexual excesses and abuses. These are a copious fountain of ills to humanity. A host of diseases, such as tuberculosis, diabetes, cardiac and nervous affections, epilepsy, hysteria, general debility, weakness of sight, languor and general worthlessness, hypochondria, weakness and total loss of rea-

son, and, in married life, impotence and sterility, are some of the effects of venereal diseases."

Brother sailors on the sea of life, these words of Father Coppens are my apology for taking you out this evening on those filthy oceans of venereal diseases, and pointing out to you some of the dangerous ports thereon.

For years the medical profession has been trying to arrive at some means by which these diseases could be lessened. It seems to be the consensus of opinion that legislation will do no good, and that the only way to check the onward march and frightful progress of these diseases is by educating the people to their terrible effects upon the individual affected to his family and to the State at large.

By venereal diseases is meant diseases that are brought on by venery or illicit commingling of the sexes. There are many such diseases, but we shall consider two of them this evening, syphilis and gonorrhea.

Syphilis is essentially a constitutional disease—that is, it is in the blood, and affects the whole system. It starts first as a small sore or ulcer, called a chancre. It seems very insignificant, and, to the uninitiated, of small consequence. It may appear anywhere on the body, but its favorite spot is under the foreskin of the penis. It usually heals in two to four weeks, and nothing more is thought of it. In from six weeks to three months the one who possessed such a sore begins to feel his bones ache, has slight fever, especially in the evening. In a few days a rash appears on his body. Then it is that he consults his physician. He has perhaps forgotten the little primary sore until questioned about it by the doctor. Now he has secondary syphilis, and if he does not put himself under treatment and continue it heroically for at least eighteen months he will always have syphilis.

After a few weeks of treatment all the symptoms will disappear, and he will consider himself well. But not so. Oyma has merely halted to recruit his forces and plan for another and a more severe blow. Syphilis is a curable disease, but it is seldom cured, because the patient gets tired of taking medicine, and ceases to visit the doctor's office, believing himself to be well.

Following the disappearance of the rash, there is generally a lull. Then comes the tertiary or third stage in the shape of enlarged or suppurating glands, sore throat, ulcers in the mouth, rheumatism and a thousand and one manifestations of the presence of the malady. It is in the beginning of this stage that it is so contagious, and many innocent people contract it. With a small abrasion on your lip, you may give it to your wife, your children or to any one whom you may kiss, with a mince patch in your mouth you may

*Read before the Nelson County Medical Society.

leave poison on your drinking cup or glass, and any one drinking after you is in great danger of contracting the disease. Infants contract it from their nurses. Innocent and pure wives contract it from their husbands. A syphilitic couple seldom bring healthy children to the world. Nearly every pregnancy results in miscarriage, and if the child should live to full term it is almost sure to be diseased. Morrow says: "No disease has such murderous influence on offspring as syphilis." Without doubt this disease is meant in the Bible where it is said that the sins of the fathers shall be visited on their children, even to the fourth generation.

Thirty-one years ago I visited a syphilitic hospital on Blackwell's Island, opposite New York, and the impression is very vivid on my mind yet! Those poor victims had sores on all parts of their bodies. In some of them the private parts were sloughing off, and the stench—that was before the days of antiseptics—was sickening.

Syphilis is a private disease and we have no means of collecting statistics. Tannier estimates that 7 per cent. of the citizens of Paris have syphilis. According to Weiss, there are 150,000 syphilitics in Berlin. In New York City it was estimated that 250,000, or 15 per cent. have it. Fifteen per cent. of the present population would be 675,000. Is it not frightful to think of this vast number of people in our midst, afflicted with this most loathsome and contagious disease, and nothing being done to check it?

You are perhaps ready to say that nothing can be worse—and you are right. Wars and floods are insignificant when compared with it. But what would you say if I should tell you that syphilis is all that I have pictured it and is even many times worse, yet it is insignificant in comparison with that other fruit that is gathered from the brambles of sin—gonorrhea.

"What! You do not mean to tell us that gonorrhea is worse than syphilis?" say you. "Why I would as soon have a case of clap as a bad cold." How often we hear that expression! Where ignorance is bliss, 'tis folly to be wise.

Some of the severest sufferings it has ever been my lot to witness were the result of gonorrhea. Let the inflammation travel back to your testicles, as it frequently does, and you will conclude that a bad cold would be a pleasure in comparison. I had a young man patient in a boarding house conducted by a widowed lady. He kept up so much complaint that she was alarmed and asked me if he was dying. A married lady contracted gonorrhea from her husband. It traveled back to her ovaries, and her sufferings were frightful to witness. Gonorrhea can and does

cause suffering of the severest kind, but still it would not be so bad if it were confined to the men who associate with the women of the street. But, as some one has said, "Like the daily bread, the man divides it with his wife." Morrow says: "No other disease has such a destructive influence on the health and procreative function of women."

Is it widespread? It is admitted by most modern writers that it is the most universally prevalent of diseases or disorders. It is estimated that 75 per cent. of the male population of our cities have had gonorrhea at some time in their lives, while only 5 per cent. to 18 per cent. have contracted syphilis. Noeggerath has stated that of every 1,000 married men in New York, 800 have had gonorrhoea, from which the great majority of their wives have been infected. Is that not a startling statement, and coming from one who makes a specialty of this disease? We are bound to give it some weight. We have organized a campaign against the White Plague, but where is any one found fighting the Scarlet Peril, which is many times worse? Morrow says that his observation at the New York Hospital extending over a period of several years, would indicate that fully 70 per cent. of all females who came there for treatment were respectable married women who had been infected by their husbands.

The introduction of gonorrhea into married life entails consequences infinitely more disastrous to the health and life of the mother than syphilis. She may be rendered a life-long invalid with her hope of children absolutely extinguished. Women become irrevocably sterile, not to speak of the danger to life itself, which, in many instances, can be averted only by the sacrifice of their reproductive organs.

Janet says: "If we compare, from a social point of view, the importance of gonorrhea with that of syphilis, gonorrhea is to syphilis as 100 to 1; not only from the standpoint of the number of persons attacked, but also from the standpoint of the gravity of the lesions and their perpetuity. Gonorrhea modifies, in a manner often permanent, the genital organs of men, renders them infinitely dangerous for the women they approach, causes all the pelvic inflammations which to-day give the surgeons three-fourths of their work, and conducts, finally, both men and women to sterility."

It is claimed that one-half of all the sterile women are made so by gonorrhea. Thirty per cent. of the blindness in the world is caused by gonorrhea. The father gives it to the mother, and the poison gets into the eyes of the infant at birth, causing inflammation and blindness. More than one-half of all the abdominal sections done on women in this coun-

try are required on account of infections, adhesions and pus collections due to gonorrhea. Dr. Joseph Price, of Philadelphia, who, perhaps, does more abdominal sections than any other man, says that of 1,000 such operations in his practice, 950 were attributable to gonorrhea. This takes into consideration only the women actually mutilated by the surgeons. No accounting is made of the larger number of infected women who are not operated on, but remain under the care of the family physician, dragging out a miserable existence of semi-invalidism, suffering excruciating pains each month.

As a depopulating agency gonorrhea stands at the head. Neoggerath asserts that 50 per cent. of the sterility in women is caused by gonorrhea. Among 81 married women affected by gonorrhea, 49 were absolutely sterile. The remaining 32 had borne only 39 children. Neisser declares that more than 45 per cent. of involuntary childless marriages and limitation of the number of children is due to gonorrhea and its sequela in man and woman. Lierascher found that out of 227 women, 121 were sterile because of gonorrhea. Gruenewald reports 53 per cent.; Kammerer 83 per cent., and Chrolok 40 per cent. of sterility in women caused by gonorrhea, while Williams insists that 73 per cent. of all abortions are due to inflammations arising from gonorrhea.

Syphilis poisons the fountain head of life. It may run on for years and finally be eliminated, but gonorrhea, by inflammation and adhesions of the tubes in both men and women, effectually and permanently dams up life's fountain head—and oh, what a damned dam it is! Don't stop your crusade against the White Plague, but at the same time take up arms against this many-times worse enemy of humanity, the Scarlet Peril.

Garrigues reports the following: "I knew a girl in perfect health, of great beauty, of Jynnesque proportions, combining muscular strength with regularity of features and graceful movements, possessing a most amiable disposition—in brief a paragon of a wife to make a husband happy. She married an excellent young man in a good business. It was a marriage based on mutual affection and held out every promise of a long and happy union. A week after her marriage she came to me with an abscess in one of Bartholini's glands and a profuse discharge from the uterus. She was under treatment for months. The abscess was opened and drained; the uterus was daily washed out with powerful germicides, ennetted and drained and finally treated with electricity. During her menstrual period she was seized with violent pain in the lower part of the abdomen, and had a temperature of 105 degrees F., with a pulse of

140. Two days later a swelling appeared in the pouch of Douglas. In a few days more the swelling appeared three inches above the pubis. An incision in the vagina gave exit to a large quantity of pus. The peritonitic infection continued to spread, and laparotomy was performed. Some pus foci was opened, but the appendages were found to be so imbedded in a mass formed by the uterus, the intestines and newly formed tissues that their removal was impossible. Finally she died."

Prince A. Morrow reports this case: "A young man whom I had treated several years previously for syphilis and discharged cured, came to me four years after I had dismissed him, stating that he was to be married in a month, and wished to know whether there was any danger of infecting his wife or contaminating his children with syphilis. As he had had a thorough treatment and a long exemption from accident he was assured that he could marry with safety. Just as he was leaving he remarked, 'Oh, by the way; I have had a little gleet discharge for three or four years. I suppose that will make no difference.' He was assured that it might make a great difference. Examination showed that he had a couple of strictures, with abundant filaments in the urine, containing gonococci. Upon my protesting to him that marriage in his present condition was impossible, he insisted that it must go on, that all the arrangements were made, and that the wedding could not be postponed. It was then explained to him fully the probable and almost certain infection of his wife, with serious consequences, but it was evident that the statements were received with downright disbelief. He assured me that he had had frequent intercourse with women, and knew that they had not been infected by him. He was deaf to all expostulations and protests. The marriage took place at the time appointed. A few weeks later he sent for me, saying that his wife was suffering horrible pain. Upon my visit I found a beautiful young woman doubled up with peritonitis, with a profuse purulent discharge from the urethra and neck of the uterus, with evidences of purulent salpingitis. She was desperately ill for some two or three weeks, and then got better. At his express insistence she remained under my care for nearly a year. During that time she was an invalid, scarcely able to walk, spending most of the time on a sofa, and at each menstrual period there was a recurrent attack of purulent inflammation of the tubes and ovaries. He was finally persuaded to consult a gynecologist, but as both he and his wife were anxious to have children the operation was deferred. She was a confirmed invalid for three years, and finally had both ovaries removed. She is now in miserable health, and

will probably remain a life-long invalid."

These two are not extreme cases. They are average cases, taken from every-day life. Nor are they rare cases, but all too frequent. Every physician with experiences meets them, often. Why, sir, since you appointed me to write this paper, I was called seven miles to the country—and the country is supposed to be almost free from this peril—to see an elderly lady with the attending physician. He gave me no hint as to his diagnosis. I had never seen the people before, and did not see the husband then. The woman was very ill, the day before her temperature had been 103 degrees F., abdomen very tender and sore, a distressed countenance. Let me tell you in technical terms the course of her complaint. You can follow and understand them. It began with a severe vaginitis, then cervicitis, endometritis, salpingitis, oophoritis, and a circumscribed peritonitis. In short, she had a gonorrhea as a present from her husband from a prostitute. There could be no mistake. The picture was too plainly drawn. Her daughter was attending her. Small children, playing in the room, called her "grand-mother." The beastly husband, father and grandfather had degraded his wife to the level of the woman of the street. Beastly! Just the same as 75 to 90 per cent. of us are. "Oh, what men do; what men dare do, what men daily do, not knowing what they do!"

When I told you we would navigate filthy seas, perhaps you did not comprehend, and perhaps now you are fearful lest we all be swamped. Let's pull for the shore.

Young man, it pays to be continent. Our passions were given to us for a noble purpose, the propagation of the race, and not to bring suffering and degradation upon ourselves and those nearest and dearest to us. I know your passions are strong, but reason and judgment are placed as guards over them, and with sufficient strength to control them, if used at the right time. Treat every young woman like you would want other young men to treat your sister. If you always do that, you will never have a case of elap. Don't say that the woman seduced you. The women who make advances to men before they have been ruined by some other man are so rare as to be curiosities. Some of you may doubt that statement, but over thirty years of experience and observation have confirmed me in that belief. If she makes advances it is your duty to yourself to beat a hasty retreat, and do not stand on the order of your going, for you may be sure she is rotten. Would you hasten to run if you knew she had smallpox? She is the hotbed of a disease many times worse.

Many men boast that when they want anything, they go where it is for sale and buy it. They at the same time get a through ticket

to hell, over a very rough road. "But I am careful, and never touch a woman unless she has a doctor's certificate that she is all right." No doctor can truthfully say that she is all right. The disease may be, and usually is, so hidden that he could not discover it with a microscope. The doctor who gives those certificates is the devil's agent, and will do all the lying his master requires of him. Don't be led astray by a doctor's certificate, for it is not worth the paper it is written on.

A young man came to consult me about some ailment. He said he had consulted another physician some days before, who, after listening to his symptoms, said, "Charlie, do you get enough?" We are taught not to judge, lest we be likewise judged, but I would tremble if I ever advised a young man to be immoral for the benefit of his health. Besides the immorality such conduct is prejudicial to health.

I began this paper in the words of Father Coppens, and I cannot better end it than in his words that follow:

"Venereal excesses undermine the vigor of the constitution, bring on a host of bodily infirmities, exhaust the system before the proper time, debauch and degrade the mind and will and prepare their victims for an early grave or a decrepit old age. On the contrary, personal purity promotes health and vigor, lends beauty to the form, gives a keener edge to the intellect, adds energy and brings success to manhood and prepares for an enduring and honored old age.

ONE YEAR EXPERIENCE WITH "SALVARSAN."

By D. H. MCKINLEY, Winchester.

As our medical journals have been crowded with hundreds of articles on "Salvarsan," it is not my intention to inflict a voluminous discussion of this subject upon you, but merely to give a brief summary of my personal experience with this remedy during the past year.

On January 4th, 1911, I gave two cases of secondary lues an intra-muscular injection of 0.6 gm. each, in alkaline solution, and shortly after a case with pronounced tertiary lesions received the same treatment. Since this time I have used the intra-venous method exclusively, employing the Heidingsfeld apparatus for this purpose, and to December 1st, 1911, have administered "Salvarsan" to the following twenty-seven cases.

One primary, one of malignant syphilis, ten presenting active secondary lesions, seven presenting active tertiary lesions, eight of la-

*Read before the Clark County Medical Society.

tent syphilis of from six months to five years' duration.

Two of the secondary cases, in both of which mercurial treatment was discontinued, showed a return of a positive Wasserman reaction, one in four and the other in five months. Both were given a second dose of "606" and mercurial treatment instituted. In the malignant case, which was referred by a local physician, and which had resisted the usual treatment, the result was brilliant, but temporary, this patient had an infection of four months' duration, of a most malignant type, with a severe syphilitic iritis. All symptoms had vanished within a week, when I lost sight of the case, but I am informed that there was a recurrence five months later. While not cured, this patient's eyes, and probably his life was saved by the one treatment. These three are the only cases that have relapsed.

Perhaps the most interesting case in the series was that of a woman, four and a half months pregnant who came under the care of Dr. Howard Lyons. This was one of those pitiful cases in which the husband after receiving a very brief and inefficient mercurial treatment, was pronounced cured by his physician, and believing this to be true got married. On August 19th, Dr. Lyons and I gave both husband and wife an intravenous injection, the former 0.6 gm. and the latter 0.5 gm. Both presented typical secondary cases, with eruptions, mucous patches, etc., which cleared up promptly, and there has been no return of symptoms to date, although there has been no other treatment administered.

On Dec. 31st, Dr. Lyons delivered the woman of a ten pound girl, the baby has shown absolutely no sign of lues so far and is apparently perfectly healthy. No Wasserman has been made simply because the father could not afford to pay the usual laboratory fee.

Of course none of us believe that "Salvarsan" is the ideal *therapia sterilisans magna* it was proclaimed at first to be by some enthusiasts, but that it is by far the most potent agent we have for combating specific infection (one dose equalling a prolonged and energetic mercurial treatment) I have no doubt.

In none of my cases did it fail to produce a prompt symptomatic cure, and in none were there bad results of any sort.

With a faultless technique I believe the intravenous administration of "Salvarsan" is devoid of danger, and is the treatment to be employed. We should not rely solely upon it however, but should combine with it either mercurial inunctions or injections of mercury salicylate, and in most cases repeat the dose of "Salvarsan" in four to eight weeks.

In this way I believe it entirely possible

to permanently cure the average case of lues in from six to twelve months, but of course it will take several years to prove whether or not this is true.

In cases of long standing it is probably advisable to give a course of the iodides, preceding the administration of the "Salvarsan," in order to aid in the absorption and opening up the lymph channels, in this way endeavoring to reach the more or less isolated foci.

SALVARSAN, WITH REPORT OF SOME CASES.*

By P. D. GILLIM, Owensboro.

Salvarsan, or "606" is the brilliant discovery of Paul Ehrlich, an imaginative methodical and conscientious investigator, who happened on salvarsan not by accident, but gradually worked out a well defined plan, with the results that he has given us one of the most powerful and efficient of spirochaetocides.

Salvarsan is marketed in ampoules containing six-tenths of a grain of the drug, a light yellowish powder, acid in reaction and requires an amount of careful preparation before it is ready for use.

Salvarsan has been given subcutaneously, intramuscularly and intravenously, though the subcutaneous method is not as popular as the other two methods. I have had the opportunity of using salvarsan in my practice thirteen times, and with your forbearance will report some of these cases very briefly.

Case No. 1.—Young man thirty-one years of age, initial lesion eight years previous, took intermittent treatment for about five months after infection resulting in a subsidence of visible symptoms for about two years, during which time he indulged in alcoholics at times to excess. Patient claims not to have been free from symptoms of lues in the past five years in spite of almost continuous treatment. Patient reported to me in November, 1910, having just returned from his third trip to Hot Springs. Examination revealed a body littered with scars ranging in size from one-tenth inch to three inches in diameter, his active lesions were in the buccal cavity and pharynx, his pharynx and mouth were literally covered with ulcers, he had an ulcerating gumma of the tongue, his tongue being indurated and fissured over its entire surface, this condition gave rise to a profuse and very foul smelling discharge.

I immediately placed him under treatment giving heroic doses of potassium iodide also Fowler's solution and mercury though previous mercurial treatment had so destroyed his gums and he showed such intolerance to mer-

*Read before the Daviess County Medical Society.

cury as to preclude very large doses of the latter drug.

Under this treatment the ulceration became less painful, the foul discharge subsided, deglutition and speech improved some, but his improvement ceased at this point, and finally in spite of all this treatment his symptoms increased in severity until my patient was in worse condition in April, 1911, than when I began treating him. On April 22nd I gave him an intramuscular injection of the neutral suspension of salvarsan in the gluteal muscles. Aside from a mild local reaction, and slight elevation of temperature on the second and third day, following the injection, there were no other symptoms, on the fourth day I began noticing improvement.

The condition ceased to pain, all discharge ceased and by the tenth day all sores were healing nicely, the fourteenth day found the induration in tongue gone and the healing process uninterrupted.

Two weeks after the injection I began injections of sodium cacodylate and gave three grain doses hypodermatically on alternate days until twelve doses were given. This for the purpose of fortifying and supporting the action of the salvarsan. My patient gained ten pounds during this time, and five weeks after the salvarsan injection he was positively free from all luetic symptoms and has remained so to the present time.

Case No. II.—Young man, age twenty-four years, contracted syphilis three and a half years ago, gave history of having chance followed by secondaries all of which responded to treatment with exception of occasional mucous patches in mouth, and throat which were aggravated by cigarette smoking.

Patient had in all about eleven months' treatment, ending with an eight weeks' course at Hot Springs, he had no symptoms for two years when about six months ago he noticed some pain and soreness in nose, soon followed by a very foul odor, patient complaining that the odor of his breath was sickening to him. An examination revealed a necrotic process, on the septum showing a condition which would soon develop into the typical saddle nose. On July 25th I administered an intramuscular injection of the neutral suspension in the gluteal muscles, local reaction was not severe, no general reaction aside from slight rise in temperature, on the second day, within two weeks all odor and pain was gone and an examination revealed a healthy granulating surface, at this time I began injections of cacodylate of sodium, giving light injections in all. An examination five weeks afterward disclosed no sign of his trouble. I then advised a course of mercury but my advice was not heeded, he has had no recurrence up to the present time.

Case No. III.—Middle aged man, infection dates back nine or ten years, my history of this case is meager, but I think he displayed mild symptoms occasionally during this time, family history tubercular.

About eighteen months ago he became very much worse, cerebral symptoms developed, causing him to lose his reason.

Gummata formed over various parts of his body, ischio-rectal abscess developed, periostitis in femur involving knee-joint, and a necrotic process of the humerus were two very aggravating symptoms in this case.

Under heroic and exhaustive treatment by his physician some of these conditions improved and his reason returned.

When I first saw this patient in company with his physician I found the following symptoms. Mind undisturbed, ptosis of left eye lid, iritis with fixed pupil in same eye, constant headache, periostitis in lower end of femur involving joint, three or four gummata enlargements over body, profound weakness and anemia, face and feet swollen, and a most agonizing and constant pain in area of right side which pain we afterward found to be due to a necrotic process in the humerus directly under the nerve. An intramuscular injection of five-tenths of a grain of the neutral suspension of salvarsan was given, local reaction mild, pain moderate, elevation of temperature on second and third day, a most foul smelling perspiration was also observed for three or four days. The injection had no depressing effects whatever, patient began feeling better next day, in three weeks he was much improved, the ptosis in eye had cleared up, he suffered very little pain, swelling in face, feet and knee, had disappeared, the gummata left as if by magic, general health had improved wonderfully but this condition did not last long, and while many of these symptoms did not recur, this patient's pain in arm, recurred as violently as ever, and required an operation for the removal of necrosed bone, which has temporarily relieved him, and he is gaining ground again. This in my opinion is a case for a second, and even a third dose of salvarsan.

Case No. IV.—Patient contracted syphilis five years ago; neglected treatment for the first year, but has since been under almost constant treatment, including a sojourn at Hot Springs, patient came to me for treatment six and a half weeks ago with scattered syphilids over his body and a laryngeal ulceration that had arisen over a year ago, patient told me he had not spoken over a hoarse whisper in twelve months. I gave an intramuscular injection of Salvarsan prepared in an alkaline solution. This injection produced more pain and local reaction than any of the

other cases in which I have used this drug, no general reaction.

Patient's improvement was noticeable on the third day and in two weeks all laryngeal irritation and other symptoms had subsided and his voice was clear and natural.

At the end of two weeks, I began the use of cacodylate of sodium, three grain ampules every second day until I gave twelve injections. Patient has had no recurrence at the present time.

Case No. V.—Middle aged woman, infection of fourteen years standing, took treatment for one year following infection.

Patient stated she had been free from any manifestations of her trouble for twelve years, when about sixteen months ago a granulomatous condition developed involving two-thirds of the surface of nose. Her nose resembled pictures I have seen of *granulosis nasi rubra*, and had been diagnosed and treated for various skin diseases with no benefit.

Gave patient six-tenths of a grain of the neutral suspension of salvarsan, local reaction mild, no general reaction. In sixteen days following injection the nose had entirely healed, normal in size and all that remained of her trouble was a slight redness of the skin.

There are eight other cases of syphilis in which I have used salvarsan, most of these were cases of early syphilis with active secondaries, all visible symptoms cleared in a remarkable short time.

I have used mercury and sodium cacodylate following these injections, and no symptoms of syphilis have manifested themselves up to the present time.

So much from my experience with this new drug. Now what are our conclusions concerning "606"? Is it a dangerous drug? I consider its dangers have been overestimated. It is a potent drug and would probably offer an element of danger to one showing an arsenical idiosyncrasy.

Wechselmann has given 4,500 injections of salvarsan and has never observed any toxic effects from the drug. However, some deaths have been reported after its use, but we must remember that it has been a remedy of last resort in a vast number of cases, and the deaths due to this drug have been relatively few as compared with the deaths following the intensive use of mercury, about eighty deaths are on record, due to the injection of the mercurials alone. Both Erlich and Wechselmann regard salvarsan no more toxic than our old friend mercury.

My paper has dealt with a new remedy which has not definitely found its place in modern medicine, but from my brief experience with this drug and the vast experience of others, I am convinced that Erlich's sal-

varsan is not a *therapia sterilisans magna*, but a most powerful weapon in the treatment of syphilis. It has not rendered mercury and iodide of potassium obsolete and never will.

And not unlike the administration of any powerful drug, must be given properly if given safely.

ANIMAL EXPERIMENTATION; ITS CONTRIBUTION TO MEDICINE AND SURGERY.*

By W. E. SENOUR, Bellevue.

Recent progress in medical research is one of the most extraordinary achievements of the present century.

Such research is absolutely the most humane of human occupations, because it has prevented human suffering and death upon a most extensive scale, and because it promises to achieve in the future greater triumphs over pain and death.

Observation and experiment alone have furnished the real foundation for scientific knowledge. All who are acquainted with the history of science recognize the fact, that not a single one of all the great truths of modern physiology, pathology, bacteriology, materia medica, and therapeutics has been established without the aid of experimentation upon living things.

Every great advance in medicine and surgery from the time of Galen, 131 A. D., to the present moment has resulted either directly or indirectly from animal experimentation. Galen devoted much time and study to this work having made more than six hundred sections of living animals.

As a result of his labors he demonstrated that the arteries contained blood during life and not the breath of life as taught by Aristotle.

While he was lauded by many of the research workers in his time, none employed his methods, so that for many centuries we find that men were content to worship his name and doctrines; they invented theories that were no help either to science or practice. While the heart and the blood vessels were known to the ancients, yet the discovery of the circulation of the blood waited fifteen hundred years for Harvey's frequent examination of many and various living animals. About one hundred and thirty years later Claude Bernard made the first experimental studies of digestion, yet the true experimental studies of digestion as we understand it today is of comparatively recent date.

Among the ancients there was great diversity of opinion as to the nature of digestion. Hippocrates regarded it as a coction:

*Read before the Boone County Medical Society.

Galen, a fermentation as of wine in a vat; while Boerelli saw nothing more in digestion than a purely mechanical act, a work whereby the ingesta was finely divided and pulverized.

During the early part of the eighteenth century there was much controversy concerning the nature of digestion. In order to settle the controversy, the Academy of Florence offered a prize to the one producing the best work upon digestion. Tiedeman and Gmelin of Germany and Leuret and Lassaing of France submitted works of equal merit and the Academy divided the prize between them. The writings of Tiedeman and Gmelin were of special interest on account of the great number of their experiments, from which came not only the absolute proof of the existence of the gastric juice, but also the study of the transformation of starch into sugar. Then digestion was finally recognized, not as simply dissolution, but a true chemical transformation.

It was also about this time that Bernard discovered glycogen in the liver. This discovery had a profound influence upon physiology and pathology, and was a valuable link in the chain of special problems connected with digestion and nutrition. Up to this time it was conceded by those engaged in experimental work that the animal body was composed of a bundle of organs, each with its appropriate function. Such a conception did much to narrow inquiry, since when a suitable function had once been assigned, there seemed no need for further investigations. To this new function of the liver, he gave the name of internal secretion.

To-day no part of physiology is being more fruitfully studied than that which deals with the changes that the blood undergoes as it sweeps through the several tissues. The study of these internal secretions constitutes a path of inquiry, which has already been trod with conspicuous success and which promises to lead to untold discoveries of the greatest moment. Bernard also pointed out the fact that the pancreas, besides aiding in digestion, pours into the intestine an internal secretion, a constituent of the blood that belongs, not only to the digestive system but like the thyroid gland and supra-renal capsules to the whole chemistry of the blood and tissues.

By means of vivisection the physiological function of the spleen has been pointed out. It has likewise demonstrated the possibility of health after removal of the spleen. The thyroid gland was known from early times, but the discovery of its function and the consequent discovery of the remedy for myxedema and cretinism was the fruit of recent experimentation.

It was Louis Pasteur, who, less than forty

years ago, by his discoveries of the fundamental principles of modern science of bacteriology opened up a vast field for medical discoveries in the cure and prevention of disease. It was Pasteur and his pupils, who, by inoculating animals with bacillus of chicken pox, pointed out the way for the discovery of the principle of vaccination by means of bacterial cultures of lessened virulence. To determine the degree of virulence of all vaccination products used throughout the civilized world, they must first be tested upon laboratory animals. The discoveries of Pasteur gave new life to the principle of vaccination against small-pox, discovered before him by Jenner.

During the eighteenth century one in every ten deaths was due to small-pox.

To-day the average physician may practice a life time and never see a case.

It was Pasteur who discovered the effective means for the prevention of Rabies. By experimenting upon dogs and other animals, he succeeded in producing an emulsion of the brain and spinal cord of the animals, which, when injected into an animal bitten by the rabid dog, absolutely prevented the animal from contracting the disease.

Whereas, the mortality has been reduced from 50 per cent. to 1 per cent.

Stimulated by the results of Pasteur, Lord Lister experimented upon various animals with different antiseptic fluids, and from his work dates the beginning of our modern antiseptic surgery.

Prior to the experimental work of Flexner upon monkeys in case of epidemic meningitis, the mortality was 80 per cent. and in severe epidemics 100 per cent. To-day with the serum he has perfected we have a mortality of 20 per cent.

Our knowledge of tuberculosis has been greatly accelerated by experimental work. In 1860 a French investigator showed by inoculating animals with the product of this disease that it could be transferred from one animal to another; that it belonged to infectious diseases. By applying the methods of bacteriology derived from the experimental study of other diseases, the bacillus tuberculosis was discovered by Koch. Having discovered the cause, we were able to guard against infection and spread of the disease, thereby greatly reducing our mortality. It has influenced public opinion, whereas certain laws providing for the prevention of spitting in public places and conveyances have been enacted. It has brought about the present rigorous control of the meat and milk trades. While the discovery of the remedy by Koch failed to fulfill the hope it inspired, still it brought about an immense improvement in the early diagnosis of all cases.

Dr. Trudeau, one of the oldest and best known phthisiologists in this country, also, founder and director of the Adirondack Cottage Sanitarium, says, "Everything that has a direct bearing on the prevention of tuberculosis, everything that has changed man's attitude toward it, from one of apathy and hopelessness when the infective agents which produce tuberculosis were unknown, and the disease was thought to be inherited and always fatal, to the growing hope of its conquest, we owe to animal experimentation. The conquest of tuberculosis in man and animal through the production of some safe method of artificial immunity seems, even to those hitherto skeptical, no longer visionary and unattainable."

Sir William Osler, when speaking of the discovery that malaria is transmitted to man by the mosquito, said, "The discovery of the transmission of malaria by mosquitoes, the knowledge which was destined to make the tropics habitable, never would have been made without animal experimentation. The men who made these experiments had spent their lives in the research laboratories and their whole work was based upon such experiments."

Epidemic poliomyelitis prevailing in this locality but a short time ago is being studied by inoculating monkeys with the virus of the disease. Flexner has already discovered that the disease is contagious, that the causative germ of the disease is so small that even our highest power microscopes fail to give us a definite image of it.

He has also learned that the nasal mucous membrane furnishes a suitable nidus for the entrance of the germ, and that spraying the lining membrane of the nose with a weak solution of hydrogen peroxide will destroy the virus.

I am satisfied that the cancer problem which is being carefully studied in all research laboratories throughout the world will be solved by means of animal experimentation, since we have learned more from this method during the past twenty-five years than during the preceding twenty centuries. We have learned that it is possible to transmit to the dog, cat, mouse the same cancerous growth that affects the human family.

The whole pathology of Tetanus was found, proved, and interpreted by the help of experiments upon animals. Tetanus is one of the hardest of all diseases to control. The first sign of it is the last stage of it.

There is no warning; it may be a healed scratch till the central nervous system is affected with the sudden and rapidly advancing degeneration of certain cells.

A disease produced experimentally in animals offers innumerable advantages to those interested in its natural history. It often af-

fords the earliest and surest method of diagnosis, since the successful treatment of the sick is directly dependent upon the diagnosis. For it often happens that an early and certain diagnosis constitutes the difference between life and death. It is the only method of obtaining the significant stages of the disease in complete series for a more minute examination.

Only the interruption of an experimentally produced disease of successive periods in its course can afford exact information as to the exact method by which infection spreads and immunity is produced. The changes in an anatomical structure, the lesions of disease can only be understood by producing the same disease lesions in animals and studying the various stages in their evolution.

To my mind, the most convincing evidence as to the value of experimentation in the study of disease is illustrated in the case of syphilis.

During a short period of seven years from 1903 to 1910, the cause of the disease has been established. A specific reaction for its detection has been discovered by Wassermann; its successful transmission to animals has been accomplished; and a therapeutic agent of considerable value has been advanced for its treatment.

Prior to the time of the experimental method of studying disease, most cases of infections of the kidneys were supposed to take place by ascension along the ureters, but recently it has been shown that it takes place in the majority of instances through the circulation. The toxic effects of the bile upon the various tissues in case of ruptured gall-bladder has been carefully studied by injecting into the peritoneum of a rabbit.

Most advances in obstetrics are due to vivisection. Our ability to recognize the bacterial origin of puerperal infection has enabled us to overcome its former terrible mortality. Before the discovery of Lister, puerperal fever ravaged the lying-in hospitals throughout the world, and each year caused the untimely death of thousands of women in the early years of their lives. The application of antiseptic technic rendered many operative procedures safe which were formerly murdered.

The ability to recognize the bacterial nature of certain infectious diseases of the newborn, such as tetanus and umbilical infection made it possible to save each year thousands of infants, which were formerly lost.

The laboratory investigations of Loeb, Morgan, Wilson, Stockard, and many others have led to the most astounding results concerning the production of fatal deformities. These research workers have shown beyond peradventure that practically all deformities with which we meet can be produced at will

by subjecting the early ovum to various procedures. In this way it is possible to produce spina bifida, cyclops, double-headed monsters or double set of extremities as well as those lacking extremities or having accessories merely by changing the experimental condition. It has been frequently demonstrated that fetal deformities are the result of some interference with the normal growth of the ovum in the days immediately following conception.

Thus have our ideas of teratology been revolutionized. The birth of children afflicted with congenital deformities are no longer attributed to the anger of the Gods, of witchcraft or to some malign influence to which the pregnant woman had been subjected.

Our knowledge of fever, one of the most frequent as well as the most permanent symptoms of disease, the causes which lead to it, the consequences which follow it, and the methods of treatment, has been derived from study of fever produced experimentally in animals; also, our knowledge of the disturbance of the circulation which arises in consequence of diseases of the heart and blood-vessels and which has led to better methods of treatment.

The hospital records show many cases when the lives of many patients have been saved by methods of investigation which could only be carried out in the laboratory and in which animal experimentation had been utilized.

We know what has been done for small-pox, diphtheria, puerperal fever, meningitis, yellow fever, malaria, cholera, and plague. The scourges of hospitals and camps have been conquered by the genius of Pasteur and the penetrating mind of Lister. Many of Pasteur's experiments were performed upon living animals. His germ theory of disease practically applied by Lister has transformed surgery and obstetrics. What thousands revealed through animal experimentation will have died from wound infection. The truths protect generation after generation, so long as knowledge shall endure.

While much has been accomplished in abdominal surgery through animal experimentation, still many problems are pressing for solution. How may we direct the blood around the liver in case of obstruction to the portal circulation? Is a direct communication between the portal vein and inferior vena cava a feasible operation? The performance of such an operation upon human beings would be no more regardless of human life than to forbid the demonstration of its feasibility upon the lower animals. How much of the digestive tract can be removed from a mammal without permanent and hopeless impairment of the digestive function? What

and how much may be done to the urinary tract in the extirpation of disease?

Experiments upon the brain and spinal cord of animals have enabled the surgeon of to-day to recognize and locate injuries and diseases of those organs whereby they can unhesitatingly and unerringly apply his remedy to the part affected. Without such knowledge surgeons must for years blindly inflict upon suffering humanity operations unscientific in conception and uncertain in effect. Just as they did in the operation for control of cerebral hemorrhage before the experiments upon monkeys enabled them to tell just when the bleeding is taking place and just how it can be stopped.

The surgery of the chest has been elucidated and a technic perfected for all operations upon the heart, lungs, oesophagus, and cardiac end of the stomach. The feasibility of removing a portion of diseased lung, how much lung may be sacrificed without causing the death of a dog in order, for example, that we may remove the focus of a tubercular lung from a human being. The possibility of exposing the bronchial tubes for the purpose of recovering foreign bodies after failure of the ordinary methods through the mouth and trachea. The possibility of operating upon the heart in stab and gun-shot wounds and in disease. The extent to which we can expose the heart for exploration of possible lesions without causing death of the patient from exploration. The possibility of operating upon the thoracic portion of the oesophagus through the back. The extent to which thoracic operation may be carried without too great danger. The possibility of repairing damaged arteries and veins.

All surgeons should practice the great operations of abdominal, thoracic, brain, and spinal surgery upon animals before trying them upon human beings. While operations upon cadaver are of some value, yet no idea can be obtained as to the successful or unsuccessful performance of the operation. The step most essential to the success of the operation may have been omitted or it may have been badly executed. The operations upon internal organs, now possible, necessitate for safe performance, an exact knowledge of how these vital organs behave under different conditions of trauma, and this knowledge can be properly gained by testing various operative measures upon animals before trying them upon human beings.

An exact knowledge of pathology is impossible without vivisection.

The student must see things and not simply told about them. He must see, not only what has taken place, but what is taking place. The changes in the circulation which make up the phenomena of inflammation can be best

understood by a study of the circulating blood in the web of the frog's foot.

The technic of the transplantation of organs has been perfected through animal experimentation, so that to-day the kidneys, ureters, and blood-vessels may be transplanted without vascular or urethral complications, the animal remaining in good health after the operation. Thus, from a surgical standpoint, the problem of the graft of organs has been solved.

Time forbids anything but the briefest mention of many inventions of medical and surgical practice that owe a direct debt to experiments upon animals, such as artificial respiration, the transfusion of saline fluids, the hypodermic administration of drugs, the use of oxygen for inhalation, the torsion of arteries, the grafting of skin, the transplantation of bone, absorbable ligature, the rational employment of blood-letting.

The student of to-day and the physician of to-morrow, who receives his training in biological laboratories, is trained to see, hear, and feel the throb of the internal machinery of life in such laboratories can not help possessing greater knowledge and approach his patients with keener sympathies than one who has not enjoyed such advantages. Such training makes it possible for the young man to acquire the knowledge and experience so necessary for treating his patients successfully, and his sense of responsibility for human life. His feeling of sympathy for all living things have been made keener rather than duller as the anti-vivisection would have you believe.

I am satisfied that Biology refines what is most human in man. These discoveries have not only diminished the immediate danger of disease, as for example, but has so improved our hygiene and sanitary knowledge that whole nations and continents are freer from epidemics and scourges.

A Tuberculosis Directory—Containing a list of institutions, associations and other agencies dealing with Tuberculosis in the United States and Canada. Compiled by the National Association for the study and prevention of Tuberculosis, by Philip P. Jacobs, Ph. D., Assistant Secretary, 105 East Twenty-second Street, New York.

This is the third work of its kind that has ever been published and is an authoritative list of anti-tuberculosis agencies in the United States and Canada. It gives a most complete survey of this great field of social work. The book is furnished to the public at the lowest cost 50 cents postpaid. No attempt being made to obtain a profit from the sales.

SANITATION IN SCHOOLS.*

By BRADFORD WARREN, Crab Orchard.

Having been assigned the subject of "Sanitation in Schools," I shall mention a few of the unsanitary habits and conditions now existing. A correction of which would establish conditions more favorable to the health of all concerned. I shall mention conditions as I see them now from a physician's view; and have seen them in the past from the teachers'.

To my mind the evil of first consideration in establishing conditions unfavorable to good health in school children is that of uncleanness, particularly the unwashed hands and faces of the pupils from the time they arise in the morning, all through the day, until late in the evening when preparing for the evening meal. Possibly not until they arise the next morning. With this condition existing, there is a period of twelve hours and possibly twenty-four for the germs from hands and books of many of the boys and girls and from different homes to be mixed, and find lodgment in the system, causing some constitutional disease—probably typhoid, meningitis, diarrhea, tuberculosis, etc., or more probably one of the diseases caused by intestinal parasites. Or the germ may find lodgment in the mucous or skin surfaces, the result of which may be an epidemic of conjunctivitis, or it may be scabies, to cause annoyance and mortification wherever found.

Erysipelas, ring-worm, and many other diseases may be spread by such uncleanness. This habit and condition can easily be corrected by having a few wash basins at each school and have each family furnish its own soap and towels. The teacher should see that they are properly used.

An evil of no mean importance in spreading disease is the manner in caring for the child's dinner. Usually his lunch basket sets on the floor of the school room from eight o'clock until noon. While there it is visited and contaminated by flies, ants, bugs and possibly many other disease carriers. When the child eats his dinner he is generally generous enough to exchange both lunch and disease germs with his friend. The possible result is a spread of typhoid, tuberculosis, pneumonia, meningitis and other contagious diseases. The child who must take his lunch to school because of distance from home, should have a clean substantial lunch and it be placed in a sanitary provision box at school until he has washed his hands and is ready to eat it. Pupils should be taught the danger in exchanging food—particularly biting from the same apple, eating from the same fork or spoon, etc.

In close connection with this evil is that of

*Read before the Pulaski County Medical Society.

all pupils using the same drinking cup. Only recently have I treated several cases of stomatitis in one school district. Upon investigation I found the school supplied with two drinking cups—one within the house and one at the well. Individual drinking cups will stop this source of disease.

Another evil of great importance is the habit of pupils expectorating upon the floor. I have never seen the habit absolutely controlled, especially during recess hours, when the transgressor may not be seen. This one transgressor may be the cause of several late cases of tuberculosis. I shall not mention other diseases that may be spread in the same way, consumption being far in the lead. Proper education will soon correct this evil.

Another evil, the correction of which is far from receiving a due consideration, is the use of the broom. Mr. Webster, in his famous "Blue-Backed" spelling book, said (and as bacteriology was then unknown, I take it that he said it advisedly) that "The new broom sweeps clean." That sentence is partly true in another sense than the one usually attributed to it. There has been many a loving child swept from the condition of health to one of disease, yes, from health to the grave, by no other means than the broom in the hands of a well-meaning teacher. In the country schools many of the teachers do their own sweeping and at a time when all pupils may be present, even perhaps at time of lunch. Some boys and girls are so uneducated or so unthoughtful as to use straws from the broom as toothpicks. This is a nasty filthy habit and may be the beginning of serious and fatal disease. To correct such evils the broom must be completely destroyed. The floor-mop must take its place.

The slate and sponge are excellent culture media for the growth of bacteria. The tablet is far the more cleanly.

The water supply for the home has been publicly discussed, and what was said from that stand-point is especially applicable to the school.

Other topics such as location, drainage, lighting, heating, ventilation, etc., I shall give only passing mention and leave for others possibly for some teachers to discuss. The disinfection of all out-buildings must be complete if we prevent disease.

School rooms fumigated. They contain millions of bacteria, varying, members of flies and other disease carriers, all of which are destroyed by fumigation. The teacher can easily fumigate by leaving a few pounds of burning sulphur in the tightly closed room over night. The door and windows can be opened early next morning for ventilation.

I can see only one general solution to this proposition of sanitation in schools. When

it is carried out successfully, we shall have more satisfactory conditions in the homes also for the prevention of disease. Then will the people begin to realize the importance of preventive medicine.

The solution of this proposition is the establishment of a health department in our schools, which is under the supervision of a competent County Board of Health or Health Officer. Under the supervision of this organization we should have physicians visit schools regularly for inspection and deliver lectures and instructions and make demonstrations of the cause and prevention of disease. In this work the field is sufficiently large to justify weekly or bi-weekly professional visits from the physician. I do not mean to say that the County Health Officer or any physician under his supervision should do this work without remuneration. The health officer should be able to devote his entire time to this work.

When we begin to secure sanitation in schools, among the boys and girls of to-day who are the men and women of to-morrow, then shall we begin to see the results of our efforts at preventing disease.

Parents, let me urge you to unite your efforts with us and use all your influence to establish, in your schools, conditions which will be favorable to the health of your children. Get yourselves together and get out of that "cranky" idea that "what was good enough for you is good enough for your child." Some parents still hold that idea, and while the physicians are doing their utmost to fill the world with those of sound body and mind, these same parents are doing their utmost to fill the world with invalids, fools and criminals, through their gross ignorance. Therefore a conflict is on between such parents and physicians. Let us follow to its close and hear for the physicians "Well done thou good and faithful servant, enter ye into the joys of the victors," and for such parents, "I wot that ye did it through ignorance as did also your parents." If you heed not duty's stern demand you will at the end of your career, hear from the Great Physician, "In as much as ye did it not to one of these, my little ones, ye did it not to me."

Massage of the Nerves.—Joffe relates experimental research which demonstrated a markedly injurious action on nerve tissue from pressure such as is applied in the modern "pressure massage" treatment of neuralgia. Fifty-two experiments showed that the benefit in neuralgia is due to blocking of certain of the nerve fibres from degenerative processes. The centrifugal fibers seemed to suffer more than the centripetal.

FIVE MONTHS' EXPERIENCE IN A TUBERCULOSIS SANATORIUM.*

By THOS. S. TALBOTT, Bardstown.

At the request of your secretary I submit to you this paper on the above named subject hoping that it will prove not altogether uninteresting. I will ask you to overlook any deficiency that may come to your notice on the plea of inexperience on my part in this line of work.

My case dates back to about the first of April of this year, 1911. I was attending medical college at the time in Chicago, spending a major part of the day in the class-room, or in my room at the lodging house. Take such an environment as that in which I was living at the time—six to eight hours in a medical school class-room, the balance of the day and night in a stuffy lodging house, with little or no exercise, and with my lungs laden with tobacco smoke the greater part of the time—and you have a most excellent display of predisposing causes of the disease I contracted. I don't think it would be at all difficult to find the primary cause—abundance of them in fact—floating around at all times in the air of that city.

I suffered an attack of la grippe about this time, April 1st, which kept me in confinement for about a week. Seemingly to have recovered from this I resumed by studies. My infection with tuberculosis undoubtedly followed this illness. I remember having a slight cough, some expectoration, that my appetite was rather poor, and that I found it a difficult task to keep up in my studies. Besides these symptoms I had at intervals of two weeks three hemorrhages and I think several night sweats. I remember one very severe one. I continued in my class room, however, for about six weeks and managed to do the work required of me. During the latter part of April and the first week of May, I had to prepare for final examinations, and it was the work of these that caused my downfall. I managed to finish about half of them when I became so weak that I realized that it would be impossible to continue them, at the same time the thought struck me that I might have something more serious the matter with me than a "bad cold." After considering the matter and recalling the symptoms I had presented the past month I came to the conclusion, very reluctantly of course, that I was a consumptive. It doesn't speak very well, I must admit, for my three years of knowledge acquired in medical schools that I failed to notice these things sooner. I haven't any excuse to offer except that I think it is more difficult to diagnose your own case than that

of another, especially if it happens to be, as it was with me, your first case.

I gave up my studies after making this remarkable discovery and came home about the middle of May. I remained at home for a week growing steadily, and I might say, rapidly worse. During that time I had no less than five hemorrhages and a severe night sweat every night. I made no pretense, however of staying in bed. I figured that I had only a short time to live, exist is a better word, and I decided to do my final existing standing up, if possible. I really did not think I would last over a month or six weeks. There is no doubt in my mind now that had I been left to work out my salvation in the way that I had started about it that week, I wouldn't have missed my guess by far. Of course I did a great deal of worrying during these days, a very great asset to the lungs in their work, let me state.

It was on the advice of my family physician that I came to the conclusion to enter a sanatorium. It was a question then whether to go out West or enter one nearer home. I consulted others who had tried both climates and it seemed to be their opinion that I could do just as well in Kentucky as any other place. They pointed out the fact that should I go West and eventually recover, it would be an impossibility for me ever to return to this climate and live. Of course, in considering the matter the expense of a stay out West was an argument against it. I finally came to the conclusion to enter Hazelwood Sanatorium, near Louisville. This I did on the 23rd of May. I don't suppose that a description of the place is necessary to most of you who are no doubt familiar with it.

It is situated on one of the many hills in the suburbs south of Louisville. The situation to my mind is an ideal one; not too far from the city to offer any of the inconveniences of the country; nor too near for the one disadvantage of a large city, impure air. There are four shacks or cottages for the accommodation of patients, and one large main building. The cottages are scattered about the grounds, none of which are any great distance from the main building. The arrangement of the cottage is simple. In a word it consists of a porch surrounding a small dressing room. Each shack will accommodate from eight to ten patients. Besides these there are several portable houses and a few tents. The institution could probably take care of fifty patients. On entering a patient is subjected to a thorough chest examination by at least two doctors, a chart being made of his condition and filed away to be compared with future charts. Examinations are made of this kind once a month. Examinations of sputum and urine are made once a month, and records kept. A

*Read before the Nelson County Medical Society.

record is also kept of weight taken every week; of pulse, temperature and respiration taken three times a day.

I can't state positively to what extent my lungs were involved when I first entered, but I am convinced that rales could be heard in almost any part of my right lung and that my left was only slightly involved. This information I gathered from remarks made by the physicians during the process of examination. I was considered by no means an incipient case.

A patient is required to spend at least the first six days of his stay in bed. If he is running no temperature he is allowed to get up at the expiration of this time. If he has temperature he remains there until it sees fit to decline, and he has gone six days normal. Normal is considered under 99. If after he becomes an up patient he should at any time register 99.6 or over he must go back to bed through the same process, that is running six normal days.

I had the pleasure of remaining under the covers for five, of what undoubtedly were the longest weeks of my life. I had at first temperature of between 100 and 101, but after a few days' rest this came down to a little above 99. There it remained for four weeks when it suddenly came down to normal. Much to my delight I became one of the elect—an up patient, and was never again bothered with that ever-bothering thing, temperature. During the weeks that I was in bed I received injections twice a week of streptococci vaccine. Whether this had any effect in reducing my temperature or not I can't say. I am rather inclined to believe that it did. I also received, while, there injections once a week of tuberculin. This is given to every patient once or twice a week unless contraindicated. It is not given where there is a very rapid heart action, nor to those patients who have a great tendency to hemorrhage. The dose is gradually increased, depending upon its action on the heart.

The liberties that a so-called up patient enjoys consist in being allowed to go to the main building for meals, a walk twice a day about the grounds, the distance governed by the patient's condition, and an hour spent in the evening in some mild form of recreation. Exercise other than walking is not allowed. Up patients are provided with recliners and are supposed to occupy them the best part of the day. The hours between one and three P. M., must be spent in bed at absolute rest. As a rule a patient is allowed to eat whatever his appetite craves, provided he can get it. In a few cases patients have to be put on diet, but as a rule the patients have the average appetite of any ordinary healthy human being. Besides the three meals a diet of an egg, raw,

and a glass of milk is given in the morning and afternoon.

I remained up for about six weeks enjoying these privileges. About the middle of the summer I had the misfortune to have another hemorrhage, although it was a very slight one, it put me back in bed for several weeks. I think it resulted from excessive exercise in throwing stones at canary birds or some such recklessness on my part.

A few words with regard to their methods of treating hemorrhage. The first thing given is a dose of aconite in some form; this, I suppose, for the purpose of lowering the blood pressure; one-twelfth heroin or one-fourth codein is given to control any cough, also acting as a sedative. The patient is to remain absolutely quiet and refrain from any coughing as much as possible. An ice bag is placed on the chest to remain there for from twenty-four to forty-eight hours. He is put on liquid diet for a couple of days at least, and he is requested to remain flat of his back until several days have elapsed after all traces of blood have disappeared from the sputum. He is then allowed to sit up a little and by degrees get back to the usual life.

I remained in bed for about three weeks. I soon overcame any setback I had experienced as a result of this hemorrhage and was feeling as well as usual in a few days. I continued to improve in every way up to the end of my stay at the institution two months later. Aside from this one mishap I think that I can say that my stay at the sanatorium was one of steady improvement. I regained my lost weight, my appetite is normal now. I had none at all when I went there. I have little or no cough and my expectoration is almost a minus quantity. I haven't had a tenth of a degree of temperature in the past five months. In this condition I returned home about five weeks ago. Since coming here I have continued the life that I led at the sanatorium and I know that I am still improving.

This is a brief history of my case up to the present time. It is not a story of any wonderful cure, the day of miracles has passed, but merely a record of an average case to be found at the institution.

APPENDIX BY H. D. RODMAN, BARDSTOWN.

This patient is 22 years old; six feet three inches high, and is now, January 8th, as heavy as he ever was. I have had this case under close observation since May 15th, last, when he first called on me, and when I advised him to go to a sanatorium. From a sanitary view his home surroundings were good; there never was tuberculosis in the family, and he had no association with tuberculosis patients unless it was during his school life of four or five years in Chicago, where, in my judgment,

he contracted the disease. It is more the result of the sanatorium treatment that I wish to speak. He went to the institution in a bad condition and growing constantly worse, as he tells us in his paper he had given up to die, and I believe would now be dead if he had been left alone, but instead of being under the sod, he is now a hale, hearty, stout young man, ready to pursue his medical studies.

Gentlemen of the profession it is our duty to advise, and urge these patients to go to a sanatorium and be cured. If the patient can raise only \$50.00, tell him to spend all of it at a sanatorium in learning how to live. I know of six who went from our county to this same sanatorium, three came home cured, one very much benefited, one who was moribund when she went there died, and one is there now improving. The great number of deaths from tuberculosis is appalling. Read the reports of vital statistics in Nelson county for the first eleven months of 1911; there were reported 246 deaths, 39, practically 1-6 were from tuberculosis. If these cases could have been cured (as has been the case in this same county) how gratifying it would be. Doctors don't let your tuberculosis patients sit down at home and die, when they can surely be cured. I, for one will welcome the day when the State establishes and maintains a tuberculosis sanatorium.

HOW TO PREVENT TUBERCULOSIS.*

By J. H. HESTER, Munfordsville.

Man has ever sought to discover and evade those dangers that weaken and destroy his efficiency. Since Adam was expelled from the garden of Eden and trouble first began, mankind has been threatened with two classes of danger. One is rampant; and the other, insidious. Tuberculosis belongs to the latter class.

Those dangers that we may designate as rampant, such as war, rapine, or social disorder are overt in their nature and thus the layman as well as the scientist may trace their course and discover means of preventing them: But not so with insidious and occult dangers. The occult and insidious nature of tuberculosis in its incipency render its treatment and prevention possible only by the most careful methods.

In tracing the history of tuberculosis it is interesting to know that Hippocrates, who lived 400 B. C., and who may truly be called the "Father of Scientific Medicine," spoke of consumption as a disease which is "the most difficult to treat, and which proves fatal to the greatest number of people." Isocrates also a Greek physician, who lived about the fifth century before Christ, was the first to

write of tuberculosis as a disease transmissible through contagion. In the middle ages the celebrated physician, Montano, declared consumption to be one of the most dangerously contagious and most easily contracted of diseases. In Naples a royal decree, dated September 20, 1782, ordered the isolation of consumptives and the disinfection of their apartments, personal effects, furniture, books, etc., by means of vinegar, brandy, or lemon juice, seawater or fumigation. Any violation of this law was punishable by fine and imprisonment. But the medical men of antiquity made the same mistake that the medical profession is making to-day, that is in appealing to the adult instead of the child.

To my thinking the best means of preventing tuberculosis is to inculcate the preventative methods into the receptive mind of the child. And the only effective way to reach the child is through the public schools of our country. J. Dorman Steel put his treatise on the evil effects of alcohol in the common school physiology twenty years ago, and the boys who read them are voters to-day, hence the world goes dry.

The best method of getting any effective means for the prevention of tuberculosis would be in the form of a book entitled "How Preserve Our Health" or some such title. This book should be a treatise, in language intelligible to the mind of a child, on tuberculosis, typhoid fever, diphtheria and other infectious diseases; and in addition to the above there should be something said on the subject of the eye, ear, nose, and throat, and how care for the teeth, as the proper care of these organs is an important factor in the prevention of tuberculosis. These subjects, as you all very well know, are very important ones and are very much neglected in the rural districts of our State.

I would suggest that the President of the State Medical Society appoint a committee to arrange a work on this subject, and I would also suggest that this committee be composed of two physicians, one dentist and two literary educators. I would further suggest that after this book has been prepared that it be presented the State legislature and ask them to pass a bill adding this book to the common school curriculum of our grand old State. In the meantime we physicians should see our senators and representatives and impress on them the necessity of a work of this kind in our public schools.

The question, as to the best method of presenting this to the child, should be solved by the committee who arranges the book. However I will give you a supplement to my paper that will bring out some of the most important points that should be taught in our public schools to the little folks, as the first

*Read before the Muldraugh Hill Medical Society.

impression made on the child's mind is the most lasting one.

I think there should be one or more physicians of each and every county in Kentucky give a lecture to the teachers of our public schools at the teachers' institute during this incoming year, on tuberculosis, telling them in simplified way how to prevent the dreadful disease, giving them at the same time a copy of the supplement which I will read when I finish my paper. I was asked some over a year ago to address the teachers of Hart county on the subject, which I did, and gave them a copy of this supplement to tack up in the school room where the pupils could read it for themselves; and since that time I have been consulted by a large number of the teachers and pupils of my county as to the prevention and cure of tuberculosis. I know the teachers of Hart county are anxious to assist us in wiping this dreadful disease off the face of the earth.

But after all the masses of the people must be educated before we can conquer tuberculosis; and while this "a consumption devoutly to be wished" by all medical men; we can in the language of Sir Thomas Moremanly "wish for rather than hope to see". But each local physician can in his allotted territory go about the world doing good; and as best he can bind up the bleeding lungs of those who are afflicted, and warn those who are not, against the insidious approach of "The Great White Plague;" ever remembering that in this, medical science has for its auxiliary God's free air and sunshine.

SUPPLEMENT.

ALPHABET FOR SCHOOL CHILDREN IN THE PREVENTION OF TUBERCULOSIS.

- A is for Anybody who can help to prevent consumption, a child just as well as a grown person.
- B is for Breathing which you should learn to do deeply. Take deep breaths in fresh air often.
- C is for Conghing which you should never do in anyone's face, nor should you sneeze in anyone's face. Turn away your head and hold your hand in front of your mouth.
- D is for Don't. Don't swap apple cores, candy, chewing gum, whistles or half eaten food or anything you put in your mouth.
- E is for Eating not fruit that has not been washed or peeled, or anything that is not clean.
- F is for Fingers which should not be put in your mouth nor wet to turn the leaves of your books.
- G is for Giving good examples to your fellow pupils and playmates by being always neat and clean, just as much so at home as at school.
- H is for Handkerchief which should be used only to wipe your nose, and not your slate, desk or shoes.
- I is for Illness of other kinds besides consumption, which follow these rules will help prevent, such as colds, grippe and pneumonia.
- J is for Joints where children have tuberculosis more often than in their lungs.
- K is for Keeping your finger-nails clean. A scratch from a dirty finger nail may make a bad sore.
- L is for Learning to love fresh air, and not for learning to smoke.
- M is for Mouth which is meant to put food and drink into, and not for pins or money or anything not good to eat.
- N is for Nose which you should never pick nor wipe on your hand or sleeve.
- O is for Outdoors where you should play just as much as you can. Always play out doors unless the weather is too stormy.
- P is for Pencils which you should not wet in your mouth to make them write blacker.
- Q is for Questions which you should ask the teacher if you don't understand all these rules.
- R is for Roughness in play by which you may hurt yourself or your comrades. If you have cut yourself, have been hurt by others, or feel sick, don't fear to tell the teacher.
- S is for Spitting which should never be done except in a spittoon, or a piece of cloth or handkerchief used for that purpose alone. Never spit on your slate, on the floor, or the sidewalk.
- T is for Teeth which you should clean with tooth brush and water after each meal, or when you get up in the morning and before you go to bed at night.
- U is for Unkind which you should never be to a consumptive.
- V is for Vessels like drinking cups and glasses which should not be used by one child after another without being washed in clean water.
- W is for Washing your hands with soap and water before each meal.
- X is for X-rays which sometimes helps to discover consumption or other forms of tuberculosis.
- Y is for You who should never kiss anybody on the mouth, nor allow them to do so to you.
- Z is for Zeal in carrying out these rules.

NARCODOULOSIS.*

By J. B. BRASSEUR, Norway, Mich.

Under the neologism of this term the purpose is here to unfold a few points in the natural history of those diseases improperly called drug-habits, inasmuch as they are of importance in relation to a method of treatment which is undoubtedly new, both from the standpoint of the therapeutic agents employed, and from that of their action resulting in a prompt, painless, radical and generally permanent cure.

When one considers the widespread prevalence and the steady increase of narcotomic affections, the calamities and sufferings which they inflict upon unfortunate victims, and the dangers for society involved in the dissemination of this plague, the labor of such a study may not appear useless, and it should be rendered of evident benefit, were it shown that the many obscurities reigning in the subject have been responsible for the sad verdict of utter incurability heretofore rendered by medical science.

Narcodoulousis is established in human being, and probably in all higher vertebrates, by two classes of products, and by these two classes only, viz: A. Opium and its narcotic alkaloids, morphine, morphine sulphate, hydrochloride, acetate, codein and its salts, heroin, dionine, etc. B.. Alcoholic beverages, i. e. the solutions in various vehicles of ethylic alcohol.

Cocaine, chloral hydrate, ether, chloroform, caffeine, camphor, acetanilid, bromides, antipyrine, tobacco, if really formative of habits, are not so in the sense attributed to that word for the members of the two former classes. When speaking of a cocaine habit, therefore, we must remember that the term is taken in a different acceptation, at once from the standpoint of symptomatology, prognosis and treatment; and no end of mischief has been produced through the agency of the lay literature on the subject.

We, therefore, here affirm iteratively, and we think, that in the interest of suffering humanity, it cannot be affirmed too emphatically, that opiates and ethylic alcohol mixtures only, are donlopoetic products; or, to speak more plainly, these and these only are capable of forming the so-called drug-habits. Those are the only pharmaceutical species nowadays known, the repeated use of which, at intervals of varying lengths super-induce a certain abnormal condition of the organism, and of its vital functions, such as require absolutely the presence of the drugs in the system, in order to get it to perform the said functions, and

thereby renders the regular user of those products more really a slave to their chemical affinities, than any mute in Yildiz Kiosk has ever been to the bidding of the Sultans.

Narcodoulousis is not a habit but a disease, one of the most horrible afflictions to which human flesh is heir; and the fate of the miserable victims is so pitiful, as to command not the contempt and disgust of mankind, but compassion, solicitude and well-ordered care.

ETIOLOGY.

To prove that the usual attitude of the laity towards morphinists and alcoholists is uncharitable and unjust because based upon antiquated and wrong notions, one needs but to mention the cases of infants who have become confirmed morphinists through the milk of their mothers. One of the most awful examples to my knowledge, is that of a woman who lost three babes in succession a few days after weaning, through convulsions of an origin too obscure to be detected by the attending physician. A fourth baby was saved from the same fate by the timely administration of a hypodermic injection of morphine, following the discovery of the mother's addiction to the drug, and the inference consequent thereon. The disease is met from infancy to extreme old age, the ill-fated infant just referred to being about twenty-three (23) months old; while a recent patient was eightyone (81) years old, having taken his first dose of morphine when Fort Sumter was bombarded, April 7, 1861, and having used it continually since in daily doses varying from 16 to 30 grains. Age, therefore, does not, directly at least, play any part in the etiology.

What are the conditions antecedent to the formation of narcodoulousis? These cases are rare in which in the beginning opiates are taken deliberately with no other end in view, but dissipation of a new and alluring form, and these cases constitute about three per cent. of the grand total. Such unfortunate wretches belong either to the idle and wealthy classes, or to the fair agents of what Anglo-Saxon prudery knows under the euphemistic name of the social evil. In European countries the latter class counts the greatest number of morphinists, not to say the quasi-totality. It may be of some interest to point here to the immense difference in the number of victims of the disease on both sides of the Atlantic, respectively.

While a conservative estimate places the number of opiate users on the North American Continent as five millions; while the patients are found in every district, and in communities of every size from the farming hamlet to the state or national metropolis; on the other hand, in European countries morphinists are met only in great cities, in the classes above referred to, and exclusively

*Read by invitation before the Daviess County Medical Society.

there. This contrast may suggest reflections of great import as to the social and economic conditions underlying the superficial etiologic circumstances; and have a very significant meaning in regard to the prophylaxy. In opposition to idleness and wealth, as causal elements, must be placed overwork, and the strenuous life, such as the majority of physicians undergo. While our Brotherhood furnishes directly a large quota of the legion of narcodoulousis, it is unfortunately true that physicians are also responsible indirectly for the swelling of the sum total of these unfortunates. Owing either to negligence, irreflection or misunderstanding, opiates are administered recklessly without regard to neurotic propensities, anamnestic data, heredity, without real necessity, often with too much frequency, or in too large therapeutic doses. The administration during 6 to 8 consecutive days is sufficient to establish narcodoulousis. Be it well remembered that the smaller doses will establish the pathologic condition as certainly, as deeply and as radically as the large ones. It does not matter whether administered per os or per cutem, the affection is bound to result, from the use of the drug at intervals of regular frequency whether long or short, and patients taking opiates by the mouth are as inveterately narcodoulousists as those using them by what we call the sub-way. The patent medicines containing either opiates or alcohol have been held responsible for the corresponding diseases, also, and it is an observation only too correct that they have enslaved many children and adolescents. For this class of youth there lies also an imminent peril in the moral contagion of certain forms of literature, and there are novels and the kindred productions of the graphomania of our times which have originated mischief worse than any brand of patented or proprietary mixtures. On the same order must be placed the slumming parties of tourists and idlers through dusky quarters of great cities. Many a patient dates his enslavement from the visit paid under such circumstances, to opium smoking joints. Finally, the inordinate consumption of intoxicating beverages has often led people and more frequently professional persons to the opiates. The professional man called suddenly to discharge some responsible duty while partially intoxicated, who realizes his incapacity in that condition, will be tempted to shorten, or annihilate the period of disability consequent on his excesses, by having recourse to the powerful sedation of opiates, and, after he has experienced a single time the effect, the hour for his enslavement has come, and he will awake bound hand and foot to a fate more horrible than was once the lot of Nubian heiducks in the service of Turk-

ish pashas, or of the Congolese emmeshed in the razzias of Tippu-Tip, the great slave raider of Zannibar.

PATHOGENY.

We forbear rehearsing whatever meagre data are found in all treatises of materia medica and therapeutics, as well as in those of special pathology, or rather to use the American term, of practice of medicine, just as though practice could be learned in books. Confining our attention to points of practical import, and principally to those interested in the curative treatment, we would fain elucidate at the start, the problem of what mysterious action creates the craving for opiates or for alcoholics,—a craving so characteristic of both diseases.

This essay is the result of the compared experiences and researches of several observers, physicians and chemists protracted during a period of twenty (20) years, and covering thousands of cases of all possible types and varieties, and the result is embodied in the following remarks:

First, as to opiates, while pathologists will be interested in experimental researches concerning the series of chemical transformations which the molecules of Opium and its alkaloids undergo during their passage through living organisms; concerning the action of those toxic principles upon the tissues and various organs; and concerning the concomitant modifications of the functions; the clinician has other ends in view, and to reach them, different methods must needs be employed. The observation of individuals of both sexes at all ages, in the most diverse circumstances and in all the infinitely variable shapes of intoxication, has led to this fundamental conclusion. The gist of the whole mysterious action of opiates lies not only in the breaking up of the molecules of opiates, but in the drying up of all glandular secretions which result in the retention of the products of oxidation, contingent upon metabolism in general. We assume it is a generally admitted theory now, that the part played by the hepatic secretion in the chemical transmutations of alimentary substances has a good deal less of importance than was attributed to it by physiologists in the generations preceding our own.

The liver is rather an instrument of elimination than one of assimilation, and its principal function consists in the destruction of the multiple principles toxic or infectious formed by the oxidizing processes of digestion and the ultimate bacterial transformation of residues in the intestinal tract prior to their expulsion.

In opium diseases, the secretion of the hepatic gland is either arrested or reduced to a minimum. The same happens for the gland-

ular secretions of the intestines and annexed organs, pancreas, adrenals, spleen; hence, the consequence that the products of decomposition of ileo-colic digestion, instead of being reduced to the simplest expression and thereafter being expelled, are delayed in their progress through the alimentary tract, and in the incomplete condition of disintegration are re-absorbed under the form of ptomaines, leucamines, bacterial toxins of the most varied sorts, and intermediate products of the molecular disintegration of all albuminoids and proteids. Now, the portal system carries those reabsorbed toxic principles to the liver, which is soon saturated with them. Once this state of toxic saturation is reached, the poisons pass into the general circulation, slowly infiltrating the whole organism, while their main action is felt at first on the cerebro-spinal system.

It is here convenient to distinguish three stages in the series of symptoms consequent upon the habitual use of opiates. Following the administration of even a therapeutic dose, the effect undoubtedly depends upon the action of morphine, *as such* upon the encephalo-rachydian centers.

The second stage is that of re-actions and the symptoms thereof vary a good deal according to idiosyncrasies; it may even be lacking; but where somnolence, torpor, mental dullness and apathy exist, they are due to the paralyzing influence of opiates upon the cortical cells during that stage. It is a curious fact that of the selective affinity of morphine for the centres of the highest orders, those bordering on the very limits between the ideation centers, and the ways of conduction by the pyramidal tracts of the kinetic influx, or the so-called volitions. The importance of this observation as to the influence over the life of opiate users shall be insisted upon later. However, after or without an interval of sleep, there occurs a third stage, that of ptomainization. The action of the reabsorbed toxic substances invading the system is responsible for the indescribable general malaise increasing with the time elapsed since the absorption of the last dose of drug.

First a clammy sweating with chills, great debility, unutterable anger overwhelms the patient. The torture according to most patients observed in this stage defies description, and is only relieved by collapse, paralysis of respiratory centres and death. Having once experienced, even partially, and but in its very initial period, the hellish torments of the third stage; the patient will do anything in his power to avoid any further recurrence, and therefore to attain his end, he will be tempted to have recourse to his drug, even before there is any real danger of recurrence.

Therein lies one explanation of the con-

stant increase in the quantity of opiates taken and of the abridging of the intervals between the doses. A second one will be found in the constantly increasing accumulation of toxic products requiring more frequent dulling of the cortical asthetic centres, in order to prevent the agonizing effects on the system from entering the field of sensation and consciousness. An explanation is here found of the enormous doses taken by some patients and varying from 60 to 120 grains of morphine, and in a recent case amounting to 46 grains of heroine that has a lethal power one-third more effective than morphine. Evidently but a minimum part of the substance introduced into the system is capable of exerting its selective action upon the nervous centers, and when taken per os, can be found again in the excreta, while when taken by the subcutaneous way, it is either stored up in the liver or neutralized in the humors by an adequate antitoxine. The latter point is proved by experiments on animals. Both remarks account also for the remarkable fact of the resistance of the living organisms to such powerful agents, as the opiates have been taken in many cases during several decades without leaving any appreciable noxious sequels, and this is demonstrated by the present condition of persons cured for five years and enjoying perfect health.

It is a matter of regret that the same statement does not hold true for alcoholic beverages. The prompt elimination of the latter and their influence on the glands differentiate their action from that of opiates, as well as their phlogogenic effect upon all the tissues. Here we think a great error was inadvertently made when in order to explain the action on the organism of alcoholic beverages, physiologists and pathologists have been satisfied with the study of alcohol chemically pure. For alcoholic beverages are (or ought to be) solutions in varying proportions of ethylic alcohol in the most infinitely variegated mixtures of essential oils, coloring matters, alcohols, glycerines and superior alcohols, aldols, aldehydes and ketones, both of the fatty and of the closed chain series, and notably a very venenous aldehyde called furfural.

In a clinical study of the action of intoxicating beverages on living organisms, care must evidently be taken to distinguish accurately between the respective effects of alcohol and of the additional products. The radically different symptoms of intoxications from beer, cider, wine of Burgundy or of champagne, and from absinthe, whiskey, and gin, suggest to the clinician a no less fundamental difference between alcohol as such, and the additional products in their effects on organs and functions.

However, in alcoholism, like in morphine, the insufficiency of the hepatic gland is responsible for all the nervous effects, but from a different cause—hepatitis.

Chronic hepatitis, with the alterations of the protoplasm of the hepatic cells it involves, plays here the part of the nervous system in opium diseases over the glandular system with the same final result on the secretions, viz: their retention or suppression.

The craving is not so strong in alcoholists as in morphinists, for the reason that the elimination is more rapid in the former, and the toxins have not the same opportunity of influences on the nervous centres. Here also, there is great necessity for distinguishing between the primary actions of alcohol and additional products, and that of the results of their chemical disintegrations with the toxins resulting from lack of elimination.

SYMPTOMS.

From the foregoing remarks, one can already apprehend the symptoms of alcohol diseases, as well as their rational connection with the pathological lesions and signs of the same above mentioned.

No more in the exposition of the symptoms than in that of pathogeny will it be proper to dwell at length upon a description of semeiology, which would be only the tedious repetition of all that may be found in medical works on the subject.

A little attention to a few cardinal signs and symptoms ought generally to enable the physician who has received some training in the attendance upon patients suffering from alcoholism or morphinism, to recognize them without much hesitation, under whatever shape or variety they may be masquerading amidst the habitual efforts to conceal the stigmata of their disgrace, and such, alas! at this epoch of vaunted enlightenment, those diseases, and principally the former, are still deemed to be by an ignorant world.

A sallow and waxy complexion rendered more evident by the brightness of shining eyes in the orbs of which the pupils are so contracted as to be barely discernible, a shifting glance; a countenance in which something inexpressible betrays embarrassment or apprehension; a gait frequently hesitating; a restlessness which does not allow the sufferer to remain seated for any considerable time; either joviality and hilariousness, or melancholia and mental depression, such are the main characteristics of opium eaters and morphinists. There are exceptional cases in which the facies is congested. The patient often makes persistent but generally ineffectual efforts to act and appear as others around him. All cases are remarkable for the irresponsiveness of pupilar reflexes to the usual excitations, or at least for the slow reaction following irritation of the pupilar reflexes.

But physical symptoms are only a small part of the complex semeiology of morphine. The psychology of these patients has been considered mostly from a literary standpoint by writers of the DeQuincy class, but it holds in reserve a mine of facts as curious and unsuspected, as they are interesting for physicians, moralists and sociologists, as well as for the student of mental science.

Besides the influence of opiates over the cortical psycho-motor centres, which has been already mentioned, perhaps the most tragic effect is that which results from the slow but fatal disintegration of the moral elements constituting the best part of the individuality. The intellectual faculties may be for a long time preserved in their integrity, at least to all appearances. The character is at first modified and in a manner which may be a constant puzzle to those not informed of the diseased state of the subject, and may lead to deplorable misunderstandings. However, the most striking effect of opiates on the psychic entity, and also the origin of the most horrible sufferings, arise from the gradual decay of the moral sense: for sooner or later, the patient will feel weighing upon him the frightful obsession of his enslavement in the clutches of a tyrant more inexorable than any that ever domineered in the Orient. Sooner or later, and with an acuteness proportioned to the keenness of his faculties, the patient is oppressed with the sense of his degradation and the consequent self-contempt is only equalled by the apprehension of being betrayed and exposed to universal abhorrence, and by his utter inability to shake off the incubus bound to affect his total undoing. With the disappearance of that fundamental illusion of free choice and determination upon which practical reason has reared the whole fabric of personal and social morality and law, the relentless Nemesis dogging the steps of Narcodonolists is fast approaching the period of mental decay and moral dissolution ending in the torpid apathy of the embecile or in the insensibility of the criminal degenerate.

A comparative study of the symptoms produced in habitual users by cocaine and by morphine respectively might prove highly interesting as conducive to practical results of no meagre importance. The facies of the cocaine addict when under the influence of that alkaloid is different from that of the morphinist. Besides being somewhat congested and vultuous, there is that of indefinable in the eyes with their dilated pupils as well as in the altered features which strikes at once the experienced observer as pathognomonic. The general demeanor and deportment and the ordinary conduct of cocaine addicts differentiate them also from the morphinists. The

restlessness and polyphrasia, the loquacity or hilariousness of cocaine intoxication distinguishes it from morphinism, though the latter exhibits often, during a certain stage, symptoms of stimulation, but even these differ in a lesser intensity compensated by a longer duration. Thus the well known increased capacity for labor and endurance or hardships can only be prolonged through frequent absorption of the alkaloid. The anesthesia of the pharynx and stomach often abolish the sensations of thirst and hunger, and a complete lack of appetite may cause the victims to pass days without food, thereby adding to the nefarious action of the drug itself, the life-sapping effects of inanition. The most deadly results of the cocaine addiction are not slow to appear in the mental and moral decay, as well as in the bodily degeneration.

The mode of action of cocaine so different from that of morphine, explains why the physical cure of addicts of the former is so much easier than that of the latter.

But while the physical cure of cocaineism is readily accomplished the avoiding of a relapse is a task replete with extreme difficulties. Once the drug taken suppressed and the craving destroyed, the further and most important treatment ought to be continued for months under the supervision of specialists in mental and nervous diseases.

The destructive action exerted by cocaine on the highest cerebral centers from which result the paralysis of the will power and the disintegration of the moral faculties account both for the difficulties of the secondary stage of the treatment, and for the social peril of cocaine addiction. The annals of criminality bear witness to this statement. The morphine addict, on the other hand, exhibits a disposition to enjoy "opium cum" or "sine digitate" and would rather enjoy a peaceful quietude than "take arms against a sea of troubles."

Reflexion over the concise exposition just given will make clear the pathos or the tragic part of the pitiable lot to which cocaineism and morphinism bring ultimately their victims. The consciousness of slow degeneracy and the feeling of degradation imposed by the knowledge of enslavement without hope are sufficient to suggest what tortures undergo the unfortunate wretches addicted either to morphine or to cocaine and to awake in physicians as well as in all unprejudiced persons acquainted with those diseases, a deep commiseration, an earnest and active sympathy.

Thus, of a bright intellect often of broad and extensive culture morphine or cocaine have made in a few years a dull-eyed, slow-witted, unscrupulous and idle reprobate; of a virtuous, modest person a lascivious receptacle of impure imaginations.

TREATMENT.

Any case of narcodonolosis of whatever duration, of whatever intensity, can be cured radically, safely, and, to all practical purposes, painlessly, in a period varying from 3 to 4 days.

Not by any agent heretofore unknown, not through some new method or system of physical, electric, Christian science or chiropractical therapeutic, but simply through the rational use of such pharmaceutical species as answer to the indications supplied to the trained and accurate observer of symptoms and of their pathological meaning.

The solution of the whole mystery is contained in one word: Elimination. To expel the residues of digestion accumulated in the lower portion of the alimentary system must be the first object of the treatment, to accomplish which no more effective agents can be employed than the salines combined with some cholagogue cathartic; one may use a solution of magnesium sulphate and Rochelle salts with cascara sag. fl. extr. This will generally rid the intestines of the feces accumulated in the colorectal tract sometimes in enormous masses, by the persistent constipation symptomatic of most opium cases. But, once the obstinate constipation relieved, the elimination has not begun; the ways have simply been opened for it. The liver, stomach, intestinal glands are still holding in their natural secretions and kept locked up in the humors all the toxic principles resulting from the upsetting of the glandular functions. Consequently with the liberation of the bowel contents, and the possible expulsion of a wonderfully large quantity of residues; with the existence, it may be, of an apparent diarrhoea; we must take heed lest we consider the elimination accomplished; *it is not even begun*. Now is the time for stimulating the glandular secretions by the appropriate agents which the modern materia medica offers to our choice. Preference should be given for the purpose in view, to calomel, elaterium, podophyllin or rhenn. Calomel in doses of from 10 to 40 grains in the twenty-four (24) hours will start the biliary secretion and with it, the expulsion of the toxic materials which can be followed by observing the nature of the stool, and more evidently still in the promptly improving of the patient. Forty-eight (48) hours of this treatment, have generally ameliorated that condition so far as to allow of the usual quantity of opiate being reduced by two-thirds (2-3) without any suspicion arising in the user's mind, from the least malaise. As soon as the process of elimination of the toxins is well under way, and it is known from the alteration of facies and cornea, from the euphoria, as well as from the stools, the time has arrived for the real

cure of narcodonolosis, for cutting the Gordian knot of those bonds which have kept the victim in the miseries of servitude. The object is to suppress the irrepressible craving for the opiate engendered by the depressing and torturing effect of the toxines over the whole system. This object is attained in 36 to 48 hours during which, elimination being carefully kept up by calomel, cathartics and saline, the patient is saved from the almost unbearable torments of the ordeal, by the suspension of consciousness and with it of the sensibility to pain.

The agents at our disposal in the therapeutic armamentarium are numerous, but there seems to exist in *Cannabis indica*, and in hyoscyamus preparations a sort of antidotal property which makes them most worthy of our preference for the intended work. Refracted doses are given every 2 or 3 hours, of sufficient strength, to keep the patient in a state of semi-stupor or half-hallucination. The effect of this treatment is as follows: First dose of *cannabis indica* solution, injected in the evening, generally produces sleep of from 6 to 8 hours, although the last dose of morphine may have been given twelve hours before. As soon as the patient awakes, a second hypodermic of *cannabis* is given, then a third, and fourth, either hourly or every two hours, according to effects, which a little experience soon teaches to appreciate. From 8 to 25 injections may be needed before the full physiological effects of *cannabis indica* be obtained and if elimination meanwhile has been well maintained, the patient, after a period of real refreshing sleep, will awake clear minded and without craving, with the indescribable feeling of happiness resulting from the overwhelming sense of liberation. He is cured.

During the delirious stage, a period of 6 or 12 hours may intervene, in which the hallucinations take a more exciting form, impelling the subject to restless activity of an ataxic nature or there may be jactitation and disordered movements approaching or simulating real convulsions. But, during all this trying period the pulse is usually normal as well as the respiration. Wide dilatation of the pupils and flushing of the face, with general perspiration, announce that the desired effects have been obtained.

It may happen that at some time during the second half of the delirious period of treatment, all at once, the bowels that have heretofore acted regularly, are stopped, and the arrest of elimination with the consequent retention of toxines produces the restlessness, jactitation and spasms alluded to. No stronger confirmation of this theory needs be offered, than the immediate relief of such conditions which follow vomiting of frequent

natural occurrence in these cases, as the effect of the *vis curatiæ naturalis*, and which it may be indicated to provoke. Another proof is found in the possibility of avoiding the period of restlessness by pushing the elimination to its extreme limits. The quantity of regurgitating bile which is frequently expelled by vomiting, will astound the physiologists. It amounts sometimes to 6 or 8 quarts. Once this hyper-secretion of the liver, and all of the glandular system well started, the cure can be considered as very near completion.

Out of this ordeal the patient commonly awakes refreshed, without craving for opiates, without remembrance of his sufferings, but in a condition of weakness similar to that of a convalescent, from typhoid fever; and the treatment henceforth, will be the same.

One caution, however, must be heeded carefully in regard to the condition of the digestive organs. This condition is peculiar to the convalescence of the narcodonolosis, and owing to it neither sweet milk, grease or fatty foods must be given, nor ice water, coffee or acids; unaltered milk only must be given during the whole treatment, and the first week of convalescence, bouillon, beef tea or chicken broths, sweet fruits, toast and eggs (soft boiled). Muscular or articular pains are best treated by massage, and the persistent insomnia by hot baths, or mild hypnotics, such as *passiflora* combined with strontium bromide. Exercise in fresh air, plenty of walking out doors must be insisted upon as soon as the patient leaves the bed, that is, the second day after treatment. Our experience has led us to consider walking and exercise, in fact, outdoor life as the most powerful adjunct of all medication during convalescence, and hence the appropriateness of treating opium cases in so equal and mild a climate as to allow of this procedure during every season of the year.

The treatment of alcoholism is based upon the same principles with the single difference that it is instituted in a milder form.

Both kinds of cases can be cured completely within a period of twenty-one (21) days.

PROGNOSIS AND CONCLUSION.

From our opening remarks in the paragraph relating to the treatment, it is apparent that we consider narcodonolosis as perfectly curable as syphilis or malarial fever, with the following reserves, some of which have been hinted at in treating of the etiology.

A certain class of cases are incurable for the simple reason that they do not wish to be cured. However strange it may sound at first, a little reflection over the circumstances which have led to the establishment of narcodonolosis will explain this apparently nonsensical frame of mind. The neurotics who commenced using opiates deliberately, attracted by the

imagined seductions, heard or read of in romances, of the entrancing dreams induced by these narcotics, those persons will never be cured. The stigma of mental or moral degeneracy will be found in many cases to account for the abnormal desires of sensuality characteristic of these unfortunates. There is hardly a better prospect of relief for the wretches of both sexes, sunk in dissipation and debauchery, who took to the drug in order to find a surcease of pain and grief, to allay momentarily the qualms of remorse, and to seek oblivion in the artificially created torpor or paralysis of a guilty conscience.

All cases accidentally formed can be cured completely within a period of three weeks, convalescence included. In persons leading sedentary lives and also in physicians, active resumption of professional duties should not be thought of for at least three months.

Though our prognosis is favorable, and, indeed, most favorable inasmuch as the cure of individual cases is concerned, we are, however, constrained with deep regret to confess that our convictions as to the outcome of prophylactic measures are far from optimistic.

The diseases of both opium and whiskey shall continue to extend over this fair country of ours, despite the fact that they constitute a plague whose ravages for the individual involve untold sufferings, degradation and misery, and for society a most imminent peril.

Under the circumstances usually antecedent to the formation of narcodoulous, and constituting but the superficial etiology, a disease of such frequency, extension and persistence must be rooted more deeply and recognize its origin in the very vital parts of our social organism, in the most essential parts of our civilizations.

We are proud, too proud, of the progress realized during the past two generations, mostly in the domain of natural science and their applications to art and industries. But, in true morality, personal or social and political, what progress have we made?

The enslavement of the weaker by the stronger, of the inferior by the superior races, of the defeated by the victorious in war, appears, among the many disheartening contingencies of the universal life-struggle, as the one which has stamped most distinctly upon man's forehead the undeniable marks of his brute inheritance.

Let us remember that it was in the second part of the nineteenth century that a concerted action of the great powers was taken for the abolition of the slave trade. Let us overestimate the advance of civilization through the development of altruistic instincts and the humanizing influences of a fast improving science, let us remember that social evolution is a gradual, interrupted and very

slow outgrowth of barbarous tastes, habits and customs.

In the course of this advance one evil has hardly been suppressed but another arises that threatens to block the highways of progress. Thus, our vaunted humane spirit, altruistic feelings, philanthropy and liberalism in moral and political judgments, spring all from the very same sources wherein must be sought the primeval cause of the psychic conditions proper to our age, and in a high degree to this country, and which are the antecedent of the formation and extensivity of morphinism and alcoholism. With the first dawn of sensibility in the chaotic stages of life's phylogenic development, the Nisus of Cosmic evolution has been integrated into that perennial universally present, (*der Wille Zum Leben* of Shopenhauer). Will to live, which permeates every material system and constitutes the life of the Universe. Never before in our times, has it affirmed its existence in individuals; and, as a consequence, life, in the individual has become largely the subservience of mind to the animal instincts of sensuality and to the wild impulses of passion.

Appeals to sensuality under indefinitely varied forms, surround and infiltrate the textures of our existences. To live at any cost, to live and enjoy life's pleasures and, for that purpose, to hide or ignore its ugly sides, pain, diseases, poverty and death, to live in pleasure and enjoy life: Perish all the rest! Hence a loss of equilibrium between the conceptive and the affective faculties of the human mind, and with it the resulting rupture of harmony between the two modes of their activity, that of reason and that of sense. Hence our emotionalism, hyperesthesia, hyperexcitability, our hysterical outbursts, our anisms and the red terrors of anarchy, the spectre of which projects its terrifying shadow over the whole structure of modern civilization.

Besides these general causes of pessimistic views intermixed with all the fabrics of our civilization, there is one of scarcely less import to be found in the attitude of the medical profession towards narcodoulotic diseases and their treatment. The calamities and despair inflicted upon millions of suffering human beings by the ruthlessly cruel verdict of medical writers on the subject, would be a reflection on the profession, were they not somewhat condoned by a provision of our code of ethics recommending as foremost, the duty of ministering to the afflicted hope, consolation, and at least palliative assistance, where no more effective one can be bestowed.

Not only the unfortunate sufferers or morphinism but their parents, relatives and friends,—millions of them—have been thrown

into the agonies of desperation by the uniformly, unvarying verdict of text-book writers, essayists in medical journals, orators of our meetings. They have coolly described the divers tortures undergone in all the stages of the disease by the morphine users; they have followed them through the various circles of an inferno more terrifying than any imagined by Alighieri and over the closed portals of this hell they have emblazoned this inscription still more despairing than that of Dante: *Non guardate mai speranza voi che siete dentro*. All hope abandon, ye who are in.

As little hope we are authorized to entertain of suppressing narcodoulosis as a pandemic, so much greater must be our solicitude for individual cases worthy of compassion, and these are the immense majority.

To the constant extension of narcodoulosis implanted as it is now in our midst, there is probably no end in view but the one hoped for by Bakounine and his disciples for the term of the Russian despotism.

The genius of Hartman, the philosopher of the Unconscious and the chief apostle of Pessimism, had not reckoned with this agent when he postponed to the most distant future the stupendous catastrophe into which he foresaw in the dim remoteness, aeons ahead of us, man and his life's works vanishing into the dark gulf of annihilation through a supreme despairing act of universal suicide.

But to the pitiful wretch who suffers and wants to be cured, we must give not hope only, but assurance that he shall be cured.

*Il faut dire dans la souffrance;
Ayez espoir da nsl'avenir
Car ici-bas sans esperance
Mieux vaut mourir.*

One must say in suffering;
Let us have hope in the future!
For in this world, without hoping
Death is better.

As Horace would have said:
*Opino hoc sentit;
Moriari! Mors ultima linea rerum est.*
(Horace).

Turbidometric Tests of Milk, Blood and Other Fluids.—The fluid in a very tapering wedge-shaped vial or glass is inspected through a narrow slit. As this slit is moved upward a point is reached where objects behind become visible through the fluid which is more or less opaque at the thick end of the wedge vessel. Schlesinger says that one is able thus to estimate the fat content of breast milk and market milk and detect admixture of water, to estimate the number of corpuscles in the blood, and, after destruction of the red corpuscles, to determine the proportion of whites.

MEDICAL MISSIONS.*

By DAVID O. HANCOCK, Henderson.

I count myself happy to stand in your presence at this hour. "The building of a perfect body crowned by a perfect brain is at once the greatest earthly problem and the grandest hope of the race. If the mind, that rules the body, ever so far forgets itself as to trample on its slave, the slave is never generous enough to forgive the injury, but will rise and smite the oppressor. The morality of clean blood ought to be one of the first lessons taught by our pastors and teachers. To preserve health is a moral and religious duty. Life is not to live, but to be well."

The iron of helpless sickness and remorseless death enters deep into the heart of humanity. Whoever comes to men with weapons wherewith to fight these enemies is made welcome. There are no circumstances of human life that do not open a way for him who is willing to bear burdens and to cheer the hearts of his fellow men. The greatness which comes by service is a greatness which can constantly be exercised. There is no fixed law of mortality. The vital resources of our country, measured by earning power, are four times our wonderful physical resources. The conserving of vital resources is the larger problem of State and National efficiency.

Napoleon was about to refuse clemency to the imprisoned Williams, when the Empress Josephine, with jeweled fingers, ran down the line of petitioners to Jenner and uttered his name. The Emperor paused, and exclaimed—"Ah, we can refuse nothing to that name."

We have New Testament authority for this department of missions. Christ Himself set the example by ministering to the sick. Indeed, He cited among the proofs of His Messiahship that "the blind receive their sight, the lame walk, the lepers are cleansed and the deaf hear." Of His thirty-six recorded miracles, were not twenty-four of physical healing. And there must have been scores of others, for we read that "all they that had any sick brought them unto Him, and He laid His hands on every one of them and healed them." So our medical work is not a mere humanitarian addition, but an essential part of our Christian service. We can not pass by on the other side of countless sufferers or shut our ears to their unceasing cries of agony.

Every non-Christian land is a land of pain. All the diseases and injuries common in America, and others far more dreadful, are intensified by ignorance appalling and filth indescribable. An Oriental tour fills the mind with ghastly memories of sightless eye-

*Read to Mid-Year Meeting, Louisville Conference Board of Missions, Fourth Avenue Methodist Church, South, January 19, 1912.

balls, scrofulous limbs and festering ulcers. If your child is ill, your physician understanding the case and its remedy, the sympathy of friends and the sweet comforts of the Gospel, make the sick-chamber a place of peace and probable recovery. But "what are those marks which so thickly dot the body?" a missionary asked Dr. Neal, in China, as he examined a little girl—such a wan, pitiful little girl. "Places where hot needles have been thrust in to kill the demon which is believed to have caused the pain," was the startling reply. "What a horrible foot! ejaculated another as he looked with Dr. Avison, in Korea, at a poor fellow who had hobbled in. A fall had made a bruise. On the advice of a native doctor, oil had been smeared over it and set on fire. Dirt and flies had aggravated the resultant sore till the whole foot was literally rotting away.

But with many such memories of horror, there are also memories of medical missionaries walking through that land of pain in the name and spirit of the Great Physician, cleansing filthy ulcers, straightening deformed limbs, giving light to darkened eyes, healing fevered bodies, robbing death of its victory.

The following are the present statistics of medical missions abroad—Hospitals 576; Dispensaries 1,077; In-patients 164,751; Dispensary treatment 4,253,375; Total treatments, 7,578,942; Surgical operations (major and minor) 157,378.

I need not here review the location, manner of establishing, or support of these seats of effort. Personal initiative, energy, industry, and thrift are essential elements of successful enterprise. The Lord's business is no exception to any other. He is not going to do what we can do ourselves; He is not going to do without us, what He can do by using us. He will not rob us of a reason for our existence, of the dignity of our lives. The endeavor to inaugurate the Kingdom of Jesus Christ in the world is, from every view-point in reality, the most splendid work that can possibly be accomplished: His Universal Kingdom of Righteousness, Joy and Peace located in men's hearts. It is proven as good for trade as for sentiment. Scientists admit its influence as valuable for the evolution of the human race as the philosophy of Herbert Spencer.

The Art of Healing is an essential part of Christian service. The personal character and scientific qualifications of its representatives are unquestioned and unquestionable.

"Their eyes have the beauty of kindness and patience from experience of human weakness and trouble of all sorts: keen and penetrating as having looked through the mists of pain and disease searching for hope,

aye, and finding it, too, sometimes, where others could find only despair; brave and steady, as having met death constantly face to face; clear and good as having looked through the glorious glass of science, and seen, more plainly the more they looked, the working of the Everlasting Arms: for surely when science brings confusion and doubt, it proves that the eye of the beholder is dim or distorted, or that he is too ignorant to use the glass aright."

Mission work is Domestic and Foreign; at Home and in Heathen lands: It is conceded the work of the Church and its authorized representatives. Of them in more recent years laymen have come in for an important part and physicians and surgeons as valuable adjuncts. The object of all being the betterment of mankind and primarily the conversion of the world,—the saving of souls.

There is a field of human effort which may more, strictly, and properly be termed Medical Missions. This is originally in charge of the medical profession. But which has been the more successful as laymen and the church have been enlisted in promoting its purposes. These purposes are essentially the same as those of the church;—economic, humane, Christian.

A great work is being done. *The vital resources of our country are four times our wonderful physical resources.*

Senate document 419 of 1910 states that at all times in the United States about 3,000,000 persons are seriously ill and that half of this illness is preventable. Appraising each life lost at \$1,700.00, and each year's average earnings at \$700.00 *the economic gain possible annually from preventing disease could exceed a billion and a half.* The real waste can only be expressed in terms of human misery. "It is in the power of man to rid himself of every parasitic disease." *Fifteen years at least could be added at once to the average of human lifetime by applying the science of preventing disease. More than half of this additional life would come from the prevention of tuberculosis, typhoid fever, and five other diseases, the prevention of which could be accomplished by purer air, purer water and purer milk. These statements are the highest authority.*

In the fight against tuberculosis during 1911 a total of \$14,500,000 was expended in this county, according to a statement recently issued by the National Association for the Study and Prevention of Tuberculosis. Of this sum nearly twelve million dollars went directly toward the treatment of patients in sanatoria and hospitals, and the remainder for dispensaries, open-air schools, publicity campaigns, and other agencies. New York raised \$3,550,000, this being the largest an-

ount contributed by any state, and Pennsylvania was second with a contribution of \$2,265,000. Appropriations of over \$10,000,000 for 1912, have already been made by the various states, and the present year will no doubt see far larger expenditures than the year just gone. The encouraging feature is that this is a winning fight that medical science is waging against tuberculosis, and there should be no lack of funds to carry on this warfare for humanity's sake.

Kentucky might profitably invest more money in this way. Our Vital Statistics Law which has but one year of service shows what we never knew before, that 30,000 people, citizens of Kentucky, died in one year.—1911, and that 12,000, or 40 per cent, of these deaths in Kentucky in 1911 were from preventable diseases; and that 5,000 of these 12,000 preventable deaths were from tuberculosis. Other equally important and practical knowledge has been given us by this Vital Statistics Law and yet there are at this moment before our legislature of Kentucky several bills to repeal this Vital Statistics Law. Is it not time for Home Medical Missionary Work? Our powers of investigation, administration and disseminating information can be adequately enlarged only by sufficient available funds, and this duty lies at the door of the State. Preventive medicine is the watchword of the hour, and enlistment in the cause can come only through education. There are two important factors in public health work. One is the gaining of new knowledge through scientific research; the other is the diffusion of this knowledge through education. The two go hand in hand. Funds, money, is the lubricator of this beneficent machinery. State appropriation is the solution of the whole matter.

It has been amply demonstrated that a large proportion of patients in the incipient stage of consumption through proper methods of living and supervision, may secure an eventful arrest of the infection. The plan of sending these patients from home for treatment has been tried out and found wanting. *We are sick of separations when the heart most needs those who love.* At this opportune moment comes the advice, "Treat them at nearby sanatoria and return them to their accustomed stations in life. *Prevention, management and treatment are the individual and social requirements of the subject.* Institutional prevention and treatment are demonstrated successes. Institutional therapeutics offer the best that is known on this subject to-day. The County-nearby-Sanatorium would meet these indications.

It seems timely that we should emphasize our present knowledge of alcohol as to *heredity, predisposition to disease and loss of*

brain power. Men who are authorities on this subject state that the disturbances of the brain by alcohol leaves an indelible impression, and that these defects are transmitted from parent to children, and that brain degeneracy exists in every child born of alcohol-using parents. In the second generation the degeneracy becomes more manifest, while as a rule it remains for the third and fourth generations to reap the full results of alcoholism. Parental intoxication tends to produce impulsive degenerates and moral imbeciles. It may not be recognized immediately, although in infancy it may show itself in convulsions, meningitis and other forms of nervous debility. Some children show signs of mental deficiency and lack of moral control, while others exhibit idiocy, epilepsy and hysteria. In a reformatory school in Berlin hereditary taint due to parental alcoholism is shown in 67 per cent. of all pupils. Of 55,000 school children examined in New York City, 58 per cent. were below the required standard, and 17 per cent. were actual dullards, bordering on idiocy.

The family history of 3,711 of these children was traced through three generations. Of the children of abstaining parents and grandparents only 4 per cent were dullards, whereas in children of drinking parents 78 per cent. were dullards, or feeble-minded. Are fathers willing to deliberately continue to bring this curse upon their offspring?

A great economic loss is the individual mental discount caused by alcohol. Psychological tests show a discount of 25 to 40 per cent. in mental power of those who use alcohol, even moderately. Sometimes the power of memory is discounted to 70 per cent. A young man starts in life with every equipment for a successful career. He takes to drink and becomes one of the ordinary or even not so much. This is the history of thousands and is a great loss to the State.

The great American fraud—patent medicine, which for so long robbed and devitalized our citizenship, is being systematically and surely destroyed.

The prevention and destruction of infantile life is receiving its just recompense of reward.

Quacks and imposters have disappeared.

Are these and kindred subjects of less importance than the conversion of the heathen? They constitute a field of medical missions which have appealed to an enlightened and aroused public. They are economic, humane, and Christian. The church, ministers, lawyers, doctors, citizens of every calling and profession are united in demanding and securing a rightful dealing with these subjects.

Now is the "accepted time" to make our

requests known. Our legislature is in session. Many of these questions will come directly before that body at this session. Each Representative and Senator is anxious to serve his constituency. The "hope of reward is greater than the fear of punishment." We shall need no Referendum or Recall if we make our request known and keep prominent the blessedness of "Good and Faithful Servant."

1. The powers of the State Board of Health, should be enlarged and its appropriation increased.

2. Adequate appropriation should be made to the State Anti-Tuberculosis Society.

3. Enabling laws should give to counties the power to provide county sanatoria, and the State should encourage the same by special appropriation.

4. One large central institution should be provided for the study and treatment of consumption.

5. The county unit law should prevail.

6. The Vital Statistics Law should be retained.

These recommendations carried out to results would mean an expenditure of an immense sum of money. One hundred county infirmaries at \$25,000 each, paid for by the county, would be \$2,500,000; one central institution should cost not less than \$1,000,000, or a total of \$3,500,000. Large as this sum is, it dwindles into insignificance when compared with the cost in human life values at \$1,700 per each one dead or, 5,000 lives at \$1,700 is \$8,500,000 loss in Kentucky from deaths from consumption alone in 1911, and \$700 annually in average wages lost. The real waste as we have said can only be expressed in terms of human misery.

We deplore the seeming deliberation with which our State handles these subjects.

Carlyl said, "Every noble work is at first impossible." Wellington at Waterloo said, "Hard pounding, gentlemen; but we will see who can pound the longest." Milton wrote, "I argue not against Heaven's hand or will, nor bate a jot of hearts or soul, but still bear up and steer right onward." We of Kentucky are as "watchmen on the wall." We should sound no uncertain note on these subjects, nor is it sufficient that we cry aloud; we must work and continue to work. Johnson wrote "Great works are performed, not by strength but by perseverance." Harvard said, "Perseverance is a Roman virtue that wins each Godlike act and plucks success from the spear roof crest of rugged danger." It was Longfellow who wrote, "The divine insanity of noble minds, that never falter or abates, but labors, endures and waits till all that it foresees it finds, or what it cannot find, creates." And from Burke we have, "The

nerve that never relaxes, the eye that never blanches, the thought that never wanders, there are the masters of victory."

THE HOUSE FLY AND HOW TO GET RID OF HIM.

By J. HUNTER PEAK, Louisville.

You have heard of "tardy information, advanced information, inside information," but I have for you tonight information on the fly, *musca domestica*.

Most people think that the world is only about six thousand years old, but that is only the recorded history of man. It is known to geologists that man must have existed long periods of years before that time.

Geologists record time by its influence upon the earth's crust and do not record time in periods of years, but in eons, or long cycles of years, and since the earth's crust has been sufficiently developed to support life, time has advanced into millions of years as we reckon time.

There is a little story extant that tells how away back in the early tertiary period, after many animals and insects had already made their advent into the world's history, that there were many more getting ready to make their debut so it was decided to hold a convention and decide the exact time for their universal appearance on earth. The fly said in his speech on the subject: "Oh, well! all you fellows may trot along, and get out as soon as you like, but man has decided to make his permanent advent into society during the latter part of the tertiary period, and I am going to make my start into the world with him," and I want to say to you that he did, and that he has been man's constant companion ever since.

In my description of the fly, I will begin at the north end and tell you about him in the order of his anatomy south, so far as it would be permissible to talk about his majesty in polite society.

The antennae, or feelers, are situated on the head and since you recognize that they are usually found on insects and lower forms of life where they have no eyes, you wonder why the fly needs the antennae since he has so many eyes. The antennae are covered, as is the whole fly, with minute cilia, or hairs. Each antenna has three joints and the antennae, or feelers, are very useful to the fly, particularly if he has happened to some accident which has caused the loss of the sight of his eyes.

We have two eyes and the glorious visions are permitted to behold in nature make us wonder what the fly's conception of the uni-

verse must be, when he has four thousand eyes on either side of his head to see with during the sunlight and three more in the center of the head to use at night, or in poor light. Scientists tell us that with all the great number of eyes which a fly has, that he can not see very well; that he is near-sighted and must have very peculiar ideas of the proportions of objects seen. For instance, if a fly is on the floor and is watching a man approach, the feet of the man look to him like huge coal barges attached to long, conical trees pointing upward and ending at the top with a very small body and a tiny ball on top of the body which answers for the head.

Some people believe that the house fly can bite and some have gone so far as to say that if a fly is infuriated that he will bite, but of all the bad things that can be said about him, that calumny should not be added to his credit. There are flies, such as the stable fly which look like the *muscae domesticae* which can bite, but if you will observe them more closely, you will find that their wings set out straighter from the body and this gives them a more pointed appearance about the head and thorax. Sometimes we find them about the house, particularly just before a rain storm. Therefore, the old saying, "Flies bite before a storm," because they can bite severely, and while they ordinarily do not bother man, yet, when they seek shelter in the house from a storm, they very naturally like to find something good to eat, hence, the fierce bite on the ankle when you have on low-cuts.

There are many other flies which you have often seen in the house, such as the small, slender lady you often find around the vinegar jug, where she deposits her eggs to be hatched out in the acid media, where they thrive and mature. Then you occasionally see the blue fly about the house. There are two kinds of this insect: a small and a large variety, which give birth alive to their larvae. They are called the blue bottle flies, and have a special fondness for decaying vegetable and animal matter, where they deposit their larvae for future development. This blue bottle fly is akin to a fly of the western plains, which also gives birth to her larvae and deposit them on fresh wounds of animals where they naturally become very destructive to the flesh and very often, if treatment is neglected, produce death in a very short time. Men, on the plains, have had the nose-bleed and have carelessly lain down to sleep, with the nose still bloody, and have waked to find themselves infected with this deadly larvae of what is commonly called in that country the "screw fly", which infection in this part of the body usually means a quick and horrible death.

But, I am about to forget my description

of our common acquaintance, the housefly. While he can not bite, don't think for an instant that he is not provided with a means of getting a living. He has a bill, or more properly speaking a proboscis, which curls up on itself so that it is almost invisible until he finds something which he wants to sample. Do you know that when it comes to eating or sampling foods, he is a connoisseur?

The proboscis is, of course, hollow, and connects directly with the alimentary tract, and he has the power to secrete a fluid of unusual solvent power, which he forces down this slender tube into sugar or other substances he wants to put into condition for swallowing. Then he has on the end of this delicate instrument two pads which close up around his food and then acts like a bulb filled with a fluid and supplied with an opening. Not only have these pads this function, but they are made like a file and the fly is able to rasp off a good meal from albuminous book-bindings and even from the kitchen table which the cook thinks perfectly clean. It is really amusing to watch the fly bother the bald-headed men who think the fly a fiend, and only wants to whiz around his bald pate to worry him, but it is not nearly so good as the edge. So also another meal which is supplied by the ingredients of the perspiration found on the man's head.

The fly has peculiar digestive organs making it possible for him to acquire a meal from almost any place and upon almost any substance, and more particularly, the products of disease and decay. You will always find him around decaying vegetables and animal matter. It has been said that he has some of the propensities of the cow. You know that if you turn a cow into a corn crib that she will not eat the corn as she comes to it, but will walk right to the top and begin there, even if it is not nearly so good as the edge. So also the fly—he wanders around over everything before he finds a place which suits him to begin eating. This habit of the fly makes him very dangerous and a menace to society.

One other peculiar thing about the fly's digestive organs is that while he can obtain sufficient nourishment to live from nearly all kinds of food, yet, his digestive fluids do not destroy the bacteria which he eats. On the contrary the bacteria, seem to multiply in the alimentary tract and pass out even more virulent, to cause all manner of trouble through the "speets" he always leaves behind. In this way, he not only infects our food stuffs with tubercular bacilli and typhoid germs, but he spreads disease through open and unprotected wounds.

The fly's thorax comes next in order of his makeup and is important for the attachments of wings, legs, abdomen and other important

organs. He has no lungs and no trachea to use in respiration, but he is fitted up with a series of small openings or tubules which pass down into the body by the means of which he is enabled to create his blood and is thereby enabled to recuperate rapidly.

The wings are peculiar in many respects. He has only two—making him a dipterous insect, but scientists tell us there was a time when he had four wings, or two pairs. That must have been when our race was nomadic and wandered around from place to place, and he had to do some tall flying to keep up with the profession, but since man rides around in carriages, automobiles, trains and steamships, the fly does not need but one pair of wings which enable him to go abroad and continue his business of being man's constant companion.

The wing of a fly is almost as thin as tissue paper and yet it has passing through it air chambers making the wing capable of inflation which keeps the wing taut and stiff. If you puncture the wing with a pin, the fly wonders what has happened, or he may think himself drunk because he can not go straight and will fly in a circle and always fall short on the injured side. You may naturally wonder how he can pump the wings full of air. Well! scientists have not named this little instrument or organ but have described it, so I will describe it and call it a bulbar, pneumatic pump, two in number, one just beneath each wing, which he uses to keep his sails inflated. You may ask "how do you know it was found out that it performed any such a function?" Well! if you injure it on one side, the wing loses its inflation and it has just as hard time trying to fly as when you puncture the wing, and goes hard to the starboard if it is the right wing or right pump either that is injured. This little, pneumatic organ has another important function. It is highly sensitive to odors. It is peculiar, is it not, to have the nose under the wing? But what is the differ nce after all, if it unerringly directs him to dinner—and I want to say to you that he can smell a good meal cooking far away. He is always on hand for the spread and, by the way, he just comes right in without invitation and takes a seat, usually on the best plate of food. He does not even have any manners though he has been associated with man so long, yet, he has never learned to wait for an invitation to sit down to dinner. In fact, as soon as he starts in, he makes a survey of everything that is not hot and does not wait for "thanks" to be returned for what he is about to receive. It is a funny thing that he does not want all the food on the table and does not eat nearly as many things as we have for ourselves, but he invariably inspects every dish and seems to take a

fendish delight in crawling over it all before you have an opportunity to begin eating and really becomes insulted if you try to shoo him away; and just to show his indignation he takes a bath in your milk or ice tea, and sometimes, in his mighty wrath, he takes his wife for a swim too. Some people say he takes her along just to take his spite out on you and does not care if she drowns, so long as he swims and can make you mad. And if you should not notice their presence in your milk and drink flies and all, well! is it not strange how one thing brings up another—and I just keep right on telling you about the interest we have in the fly instead of continuing my description of his wonderful mechanism.

A while ago, we were talking about the fly's wings, and if you will notice closely you will see a scallop in both wings and just at these points you will notice small organs, called "stoppers" which really are rudimentary wings and are the remains of the wings he has discarded in the process of the fly evolution, but they still have an important function. When a fly is going at a two-thirty gait, he can stop very quickly by turning these organs around, he simply turns the rudimentary wing to the wind on the side to which he wishes to turn. By the way, the aviator might learn a good many things from the mechanism of the fly that would aid him in constructing a scientific aeroplane. A fly can move along at about five feet per second, or he can go as fast as thirty-five feet per second, which is a two-thirty gait. The fly has the power to move his wings at the rate of six hundred and seventy-five times per second. This is arrived at by listening to the notes made by the wing vibrations and then finding the same key on the piano and you will find that it is E, first line of treble clef, which is made by six hundred and seventy-five vibrations.

To the thorax are also attached, as we have seen, the legs, six in number—three on either side. Do you know that the spider and the deer tick at one time must have belonged to the fly genesis and it is said that when the spider decided to become a wingless insect, he became the eternal enemy of the fly. It may be because he lost his wings and had to learn the new trade of spinning, a business upon which a fly looks with considerable trepidation. The fly is so afraid of a spider's web that he is very cautious of even a few strings tied across a window and the ancient Egyptians used to keep him out of the house by a simple process of imitating a spider's web made with thread in the open window. It was Demosthenes who told us about the fishermen who could not even sleep nor rest at night along some coast line, except when they would wrap themselves up in their fishing nets. The fly thought them spider-webs; hence, the fly

nets made to protect the horse. Not that a fly could not do business right down through the larger spaces in the netting, but he will not do it because it looks mightily like a fly trap made by a spider.

There are some curious things about a fly's legs and feet. The leg is strong and jointed in such a way that he can comb his head and make his general toilet with the hair brushes attached thereon. The foot has been a study a long time and very many people have had lots of discussions about how a fly can walk on a smooth glass or on the ceiling. Some said that the foot was made like a leather sucker and by exhausting the air from under the foot, thereby producing a vacuum, that the weight of the surrounding air made the foot hold. A very pretty theory! but like many other theories in this world, they have been exploded by demonstration of facts to the contrary. Then an old Swiss priest made himself famous by explaining that a fly has claws on his feet and that he could hold on to the wall by inserting them into crevices so small we could not see them. Then later on, exploding his own theory by polishing a pane of glass with impalpable powder so it would not have any place for the claws to hold to, and imagine his surprise when he thought he would fool Mr. Fly and have the pleasure of seeing him slip up and break his neck, but Mr. Fly just for a good joke started right across that glass as easy as anything. This same priest then made the statement that the fly had a power to secrete a sticky fluid by which he was enabled to stick himself to the wall. You can imagine the ridicule and comments this silly talk caused among his parishioners, but it has since been demonstrated that the priest was right in his hypothesis.

The fly has a peculiar foot under a magnifying glass. It looks not unlike the ostrich's foot with three toes and it is real interesting how he fastens his foot to the wall like a sticking plaster, and then see him remove it when he wants to move on; he does it by pulling up one side at a time just like you remove a porous plaster, by beginning at one corner.

Can you imagine a more perfect filth carrier, or disease dispenser than the gummy-footed fly? Scientists have demonstrated that you can grow almost all the known bacteria from the foot of any fly, no matter where you catch him; no matter if it were on the bleak summit of Greenland's icy mountains or on the sunny shores of some tropical clime. It has been demonstrated that you can grow on gelatin culture media not less than forty varieties of bacteria and millions of each variety by simply letting a single fly walk across the exposed gelatin media.

The time will come when no eating house or restaurant will be permitted to do business

without the proper precaution of screens for all dining halls and kitchens and then the proprietor will be made to protect all food stuffs from the menace of the fly. About the only safe way to eat now, about any eating house, is not have the waiters serve you anything that has not been well cooked and then brought to the table hot. This is obvious for if the food stuff has become contaminated by flies before cooking, the heat used in cooking would kill all bacteria and if the food is still hot the fly will not bother it except by accident.

This fight against the fly has existed for sometime in England and it is said that people are not compelled now to keep their houses screened like we do. In this country the Jewish Women's Council, the Ladies' Clubs, and various Health Boards have decreed that the fly must go, and with all that array of antagonists, I would like to know what chance the fly has anyway.

In Louisville, Dr. Grant, the City Health Officer, has introduced in the City Council an ordinance to protect the public against the fly. It makes it a misdemeanor and finable from five to one hundred dollars for each offense for anyone to allow any food stuffs of any kind to remain exposed to flies, and makes it imperative on the part of hotels, restaurants, groceries, milk dairies, and all markets to keep everything to eat well screened.

This law also makes it imperative for all stable owners to keep their stables clean and to keep quicklime thrown over all ejecta and refuse thrown out of stables or kept in receptacles and all house-keepers are required to keep the garbage-can in the same way. Of course, the first thing to do is to protect ourselves against the fly already extant in the land. The next best thing is to destroy all breeding places of the fly so he can not propagate his kind. The normal habitat of the fly is dirt and filth and he breeds best in decaying animal and vegetable matter. The fly does not like the places where cows are kept like he does a stable for horses. It has been estimated that there could be found in one pound of horse manure more than twelve hundred young flies.

The fly is awfully prolific; it has been said by Dr. Howard of the Agricultural Department of the United States Government that each female fly will raise, with good luck not less than one hundred and twenty flies in a season and when you take into consideration the fact that there can be from two to three generations of flies raised in one month, you can begin to realize what an enormous increase may occur in a few months. In addition, in the abdomen of the female fly is developed those eggs which are deposited in suitable places for future development. In about five to eight hours the egg hatches and

then it is called a larva. The larval period lasts from five to seven days and while the larvae are exceedingly small at first, they grow rapidly depending upon climatic conditions, and the media in which they are growing. Then the larvae suddenly burrow into the ground beneath the refuse in which they have grown and quickly develop into pupae and then cease to be active and hibernate from five to seven days during the pupal state, when they become full grown flies, ready for business at the same old stand. The metamorphoses is quick, complete and interesting. So prolific is the fly that it has been estimated by scientists that if a mamma and papa fly should have good success with all their progeny and none of the babies should die from infantile diseases, and they should start out on their martial life in early April, and in five months or by the latter part of August were to have a family reunion, that more than 1,700 billion would attend the family festivities. When I read that, I said that it was simply a big fish story, but I started out to make some calculations myself, and allowing only two generations in one month and ten generations in the five months, I saw that it was a mathematical problem, so I began to do some figuring, and at the beginning of June I had a long string of figures, I said that I would quit or I would have to tell a bigger one than that I had just read.

About the only way one can have any conception of such a large number is by connotations of facts we are already familiar with. A fly is one-fourth inches in length, and then it would take forty-eight of them to make one foot, if they were to stand end to end. There is 5,280 feet in one mile; then 5,280 times 48 would give you the number of flies to make one mile, that answer divided into 1,700 billions will give you 6,000,000 miles; that divided by 25,000, the number of miles around this world at the equator, will show you that this string of flies would go around this old earth more than two hundred times. Then allowing that two flies can stand side by side on a one-fourth inch space, that would give you eight flies standing side by side to the inch; hence, two hundred divided by eight would give you twenty-five inches, or you would have a patch of flies twenty-five inches wide extending around the world. No wonder old Pharaoh told Moses that he would let the children of Israel go when the flies swooped down upon him.

Then it has been estimated that four flies can occupy one-fourth inch square space, then it can readily be shown that two hundred and fifty-six flies can be made to occupy one cubic inch of space, or about 400,000 to the cubic foot. 1,700 billion divided by 400,000 equals about 4,000,000 cubic feet; 4,000,000 cubic

feet divided by 2,250 cubic feet in a room fifteen feet square, ten feet high will give you 2,000 rooms to hold that number of flies. There are about five rooms to any modern residence, then 2,000 divided by five equals 400, or 400 houses each with five rooms, 15x15x10 would be required to accommodate that family reunion of that pair of flies which had been housekeeping just five months.

But, my friends, do not take these calculations too seriously, because flies have a hard time to get along and raise a family at all. The larvae are the prey of birds and barnyard fowls and the fly himself is subject to all sorts of accidents and even diseases.

You have often seen flies standing around on window panes and look as though they had been dusted with talcum powder, well! they are sick and that whiteness is not due to being pale either, but is due to a fungus growth called by scientists *empusa*, which often becomes epidemic among the *muscae domesticae* and causes great loss of life. Then, no doubt, you have noticed that flies sometimes have red spots on them and you wonder what the occasion is for which she is painted, but that is not rouge, and the fly would like very much to get rid of her paint, or what looks like paint for that is another local manifestation or symptom of another parasitic disease to which the fly is heir and this disease destroys them in great numbers every year.

With our homes screened, we will not be able to keep all flies out so long as they exist; hence, the importance of destroying not only all breeding places, but have fly paper to catch those incarcerated in our homes.

The fly manifests but little judgment about a great many things. If you have fly paper around the house he does not notice the predicament of his neighbor which has learned too late that he can not get away, and thinking that everything on earth is made for his physical wants and to satisfy his appetite he joins his companion in endurance vile.

There are a great many poisons which a fly will eat. Some do him no harm, and that may account for his recklessness in sampling everything which looks good to him, but many of the poisons kill him, and one of the most deadly poisons to the fly is a two percent formaldehyde solution arranged in a bottle with a tight cork split on the side with a wick made of absorbent cotton, which, when the bottle is inverted, acts by capillary attraction and allows the contents of the bottle to drip out constantly. If this inverted bottle is placed in such a way that the fluid will drop into a plate every fly in the house will partake of the deadly portion and quickly die.

Psychologists teach us that man is the only animal having the power of thought, and that insects like all lower animals cannot think,

but do things by instinct and memory. This may be correct, but I could mention many things done by insects which look very much like they have some reasoning power, but I am not going to raise that question for argument, but let it be instinct or memory, the fly has learned to keep away from spider webs and if one ever disentangles himself from fly paper you could not entice him to try it a second time; likewise, he is very careful about going around anything that has a fly paper resemblance, and some have gone so far as to say that he warns all his friends about the dangerous quality of the paper trap.

While the fly is not afraid of the odor of many oils, the essential oils such as oil of wintergreen, oil of peppermint, etc., yet, he is mortally afraid of the scent of sassafras. Though none of these drugs are especially poisonous to him, yet, you know that any kind of oil will destroy not only the fly but almost any other insect if placed over his body, because if he should take a tumble into such a bath he would die from asphyxiation. You will remember that I told you that flies breathe through their skins and any substance which would close the tubules through which air passes, would immediately smother them to death.

I remember when I was a boy to have seen farmers break off sassafras limbs covered with leaves and hang them about the horse to keep away the flies. Scientists tell us that sassafras in itself, is not harmful to the fly, but there is a grayish looking spider which infests the sassafras bushes, in order to raise its young, and you may rest assured that whether it is thoughts or memory, the fly has not forgotten his old enemy, the spider, and when he scents sassafras he pulls out for tall timber. Now the oil of sassafras is not unpleasant to have around and if you are waiting to screen your house, just place on a rag some oil of sassafras and place one in each window and door and away goes the flies. If this should give you perfect protection against the fly, don't fail to screen your house, because it keeps out not only the fly but the mosquitos and other dangerous insects.

Axial Rotation of Fibroid.—A spinster, aged 67, sought Bland-Sutton's advice on account of pain, discomfort and frequency of micturition, associated with a large tumor which could be felt in the hypogastric region. It had the clinical features of a uterine fibroid. When exposed in the course of the operation performed for its removal, the tumor proved to be as big as the head of a new-born child. On withdrawing the tumor the pedicle was found to be twisted like a rope; on untwisting it the ovaries, Fallopian tubes and uterus were recognized. Subtotal hysterectomy was performed.

NEWS ITEMS AND COMMENTS

DR. M. W. STEELE has been reelected City Health Officer of Corbin.

DR. A. T. BOTTS, of Cave City, visited the State Board of Health laboratories and offices.

DR. I. W. JONES, of Owingsville, has gone to Los Angeles for his health and to take a post-graduate course.

OLDHAM—The Oldham County Medical Society met at Dr. A. E. Harthill's home in Pewee Valley, February 29th, at 1:30 P. M.

WARREN—Dr. T. O. Helm, of Bowling Green, who has been quite sick at St. Joseph's Hospital is now able to resume his practice.

DR. H. A. WILLIAMSON, an old practitioner of Boone County, has been confined to his room for some time with a complication of diseases.

DR. JOHN J. MOREN, of Louisville, read a paper on "Acute Spinal Paralysis" before the Whitley County Medical Society February 1st.

ROWAN—Dr. I. A. Shirley, of Winchester, gave an excellent lecture on "Hookworm" before the Rowan County Medical Society at Morehead.

THE Boone County Medical Society will meet in Cincinnati on the 21st inst., as guests of Drs. Langsdale and McKim. A great time is anticipated.

DR. FRED D. CARTWRIGHT, of Bowling Green, has returned from a post-graduate course in New York and Montreal and has opened an office on State street.

DR. J. S. LOCKE, of Barboursville, doing hookworm research work for the Rockefeller Sanitary Commission deserves great praise for his splendid work in the mountains.

A TELEGRAM to Dr. H. R. VanZant, of Edmonton, Metcalfe County, states that his son, Joe VanZant, of Jacksonville, Illinois, died last night. He was kicked in the head by a mule a few days ago and his skull fractured.

WARREN—A young lady has arrived to live permanently with Dr. Fred Reardon. She has not been initiated into the Warren County Medical Society but is able to cry votes for women.

DR. BENJAMIN T. NYE, 34, of Williamsburg, Kentucky, and Miss Amanda Ward, 22, of Whitley county, Kentucky, were married Saturday night in Jeffersonville by Magistrate John M. Malone.

DR. H. W. GATES has gone to Wharton, Texas, to escape the extreme cold weather we are having. He writes he will be home in April and will then send us some news items from McLean County.

MRS. CHAS. P. WEAVER, of Louisville, who lectures for the School Improvement League, and Mrs. Stewart, President of the Kentucky Teachers' Association, visited the State Board of Health Laboratories.

THE JOURNAL staff acknowledges the receipt from Mr. E. D. Chapinan, representative of the Phillips Chemical Company, a box of cocoa. It was so good that our only regret is that a sample couldn't be given to every reader of the JOURNAL. If you like cocoa, try Phillips'.

At the instance of Dr. W. R. Burr, a member of the Logan County Board of Health, one, "Dr. J. W. Moore, who gave his address as Louisville, Kentucky, was arrested and fined the limit of the law for practicing medicine without license so to do."

ACCORDING to the last census there are 130,000 physicians in the United States; this includes doctors of every description, as well as osteopaths, psychopaths, hydropaths, etc. There is one doctor to every 650 of the population and the average income of a physician is said to be \$1,200 per annum.

DR. HARRIS KELLY, former Coroner of Jefferson County and well known here, but now a resident physician of Star Ranch, Among-the-Pines, Colorado Springs, was injured several days ago when struck by a motorcycle. His condition is not thought to be serious. Dr. Kelly left Louisville several months ago.

THE County Secretary writes from Woodford County that their doctors are so busy that they have not had a meeting of the County Society for two years, and that the present officers are so popular and efficient there has been no election for going on four years. Wake up! You have a lot of good doctors

over there, why not have the best society in the State.

THERE are seventy-five cases of smallpox in Monroe County, five new cases being reported January 31. Two deaths have resulted. Sections in the northwestern part of the county are under quarantine. There is not a single case of the disease within two miles of Tompkinsville. The health officers, Drs. Morris, England and Duncan, are doing their best to keep the disease from spreading.

MADISON—The culmination of a romance which began in a hospital at Richmond, Ky., more than a year ago, came February 11th, when Dr. Hugh R. Gibson, of Richmond, Ky., and Miss Bernice Ward Orr were married at the home of the bride's parents, Dr. and Mrs. D. F. Orr. The ceremony was performed by the Rev. C. C. Orr, of Morristown, Tenn., an uncle of the bride, who is presiding elder of the Morristown district of the Southern Methodist church.

DR. W. ED. GRANT and the Louisville city health department, with the aid of the police and the board of safety, will soon inaugurate the annual spring anti-spitting crusade. Cards will be printed and distributed among citizens warning them of the law against and the penalty for spitting in public places. An effort will be made to have two members of the police department detailed in plain clothes to be on the lookout on street corners and cars for violations of this ordinance.

THE secretaries of Lyon, Nelson and Estill Counties write that nothing of interest professionally has happened in their counties. I trust every secretary will keep informed concerning the various incidents of interest occurring in the families of the physicians of their County, which would be of interest to the profession of the whole State. We want this for the News Column of the JOURNAL. Please direct all communications to the Editor, News Department, KENTUCKY MEDICAL JOURNAL.

ACCORDING to the report of the Louisville health department for the month of December, physicians are advised that Flexner's serum can be obtained from the health officer. Seventy-two deaths from cerebro-spinal meningitis occurred in Louisville last year, but none was of the variety that is benefited by this serum. The births, numbering 491, far exceeded the total of the mortality table, 278, for the month of December. The sanitary department destroyed by order of the court 580 pounds of fish, 225 pounds of beef, 3,706

rabbits, 325 gallons of oysters and thirty dozen eggs.

FOLLOWING the discovery of several cases of smallpox near First and Green streets, Louisville, Dr. J. I. Whittenberg, superintendent of the Eruptive Hospital, vaccinated fifty negroes in that neighborhood.

With a bodyguard of patrolmen, Dr. Whittenberg invaded saloons, poolrooms and other places, and wherever a group of negroes was found the policemen would guard the doors and windows while the physician worked with his needle until all in the crowd had been vaccinated.

Dr. Whittenberg said it was his opinion that the disease did not originate in Louisville, but could be traced to negro "floaters."

CASE OF PENNY WISE AND POUND FOOLISH. Several years ago the Fiscal Court of Adair County employed Dr. U. L. Taylor to furnish medical attention to the prisoners in the county jail. They gave him \$25.00 per year. He made only ten visits during the year, and they gave him the job for two more years with similar results. The court concluded then that it would be cheaper just to send a doctor when needed for a dollar a trip. They refused to make a contract for the year. There was a man in jail on a felony charge, who broke jail and was making his escape. The son of the jailer pursued and shot the man with a Winchester rifle, breaking his thigh bone. Dr. Taylor and two other doctors were employed to treat him and it cost nearly \$400.00.

DR. L. F. ROBBINS, of Salt Lick, was laid up with La Grippe for a week or two in January, but is able to be about now.

DR. JOSEPH H. SCOTT, aged 79, a retired physician, died of nephritis at his home, 950 South Preston street. He had been ill for several months. He was a native of Lincoln county and received his medical education in this State. He practiced in Kentucky and later in Texas. Ten years ago he retired and established his residence in Louisville.

He is survived by his widow, Mrs. Eunice Sharp Scott; two sons, Frank Scott and Harry Scott; two daughters, Mrs. Minnie Price and Miss Eunice Scott; a brother, Walter Scott, of Texas, and a sister, Mrs. Ella Florence. Senator W. O. Bradley is a brother-in-law of the dead man.

FAYETTE—Several prominent members of the Fayette County Medical Society, including Dr. J. W. Pryor, Dr. B. F. VanMeter, Dr. C. F. Dale, Dr. L. C. Redmond and Dr. Carl Wheeler, went to Paris February 15th,

to attend the regular monthly meeting of the Bourbon County Medical Society, and participate in the dinner which followed.

The meeting was held at the Paris Courthouse, and about fifty physicians were in attendance. The program was a highly instructive and entertaining one, and was concluded with a dinner at which the Lexington visitors were guests of honor. Drs. VanMeter, Dale and Wheeler took part in the discussion of the various papers. One of the entertaining features of the program was a humorous recitation by Dr. Keller, of Paris.

ONCE more the Supreme Architect of the Universe in his infinite wisdom has knocked at the door of the Henry County Medical Society and called from labor here on earth to everlasting refreshments above our brother physician, Dr. F. J. Yager, who departed this life in January, 1912.

Resolved, That in his death, the society has lost a true and faithful member, his family a kind and loving father and the community in which he lived a good physician.

Resolved, That these resolutions be spread on our records, a copy sent to the bereaved family, to the KENTUCKY STATE MEDICAL JOURNAL, and to our county papers for publication.

February 19, 1912.

WEBB SUTER,
A. P. DOWDEN,
Committee.

In a report on Vital Statistics Legislation it is pointed out that in only 24 of our States do we know how many human lives are lost each year; in 25 States no books are kept. In only 9 States are any birth records kept, and in most of these this has been done but a few years. In the census report for 1910 the fact appears that our death ratio is based on returns from only 58.3 per cent. of the entire population. In Alabama, Florida, Georgia, Louisiana, South Carolina, Tennessee, Texas, and Virginia an effort has been made to register deaths in the larger cities, but none has a general registration of deaths or recording of births. Proper legislation for securing vital statistics is urged in these States. Aside from the value of vital statistics from the point of view of public health, birth records have an important legal significance, as attested by the following instance: George A. Wagner of Manchester, N. H., has been elected Probate Judge of Hillsboro County, but cannot take office because no record of his birth can be found.

DR. J. N. HURTY, Secretary of the Indiana State Board of Health, delivered an address on "Preventive Medicine" before the Asso-

ciation of County School Superintendents and the Western Kentucky State Normal School at Bowling Green, on the evening of February 7th. There were about 1,200 people present in Vannmeter Hall, and Dr. Hurty's splendid address was punctuated by frequent bursts of applause. There is a quaint, quiet line of humor running through Dr. Hurty's address which made it sound all the more human and forceful. The actual experiences he told as to problems that had faced the State Board of Health of Indiana were most interesting and helpful. Everybody present voiced their appreciation of the action of the *American Medical Association* in sending Dr. Hurty to Bowling Green.

It will be of interest to everybody that Dr. Hurty carefully inspected the laboratories and Vital Statistics Bureau of the State Board of Health and was especially cordial in commending them.

The National Confederation of State Medical Examining and Licensing Boards will hold its 22nd annual meeting in Chicago, Illinois, on Thursday, February 29th, 1912, at the Congress Hotel.

The subjects to be considered at this meeting will be: The good a federation of medical boards can do; "What should be the qualifications for membership in a federation of medical boards"; "Methods of conducting state licensing examinations"; "Medical school equipment and state board license examination"; The organization of a federation of state medical boards."

The topics to be presented are practical to all those interested in medical education and a federation formed upon lines to be suggested will necessarily prove fruitful.

An earnest and cordial invitation to this meeting is extended to all members of state medical examining and licensing boards, medical teachers, delegates to the Council on Medical Education of the A. M. A., and all those interested.

The officers of the Confederation are President Charles A. Tuttle, M. D., 196 York St., New Haven, Conn.; Secretary-Treasurer Geo. H. Matson, M. D., State House, Columbus, Ohio.

PREACHING the "gospel" of good health, and with "More Life" as his subject, Dr. W. L. Heizer, State Registrar of the Bureau of Vital Statistics of Kentucky, delivered an address at the Centenarian Methodist church, New Albany. The address was under the auspices of the Y. M. C. A., and is one in a series of the Men and Religion Forward Movement.

The speaker went into detail to tell his audience that certain troubles, such as tubercu-

losis, typhoid fever, hookworm and many other diseases, were practically preventable; that the medical profession, with the co-operation of the laity, could reduce the preventable maladies to a minimum.

In the course of his address the speaker paid a very high tribute to Dr. J. N. Hurty, secretary of the Indiana State Board of Health, who, he said, has done as much probably as any man in the nation in the fight against preventable diseases.

He urged the importance of competent health officers for both city and county, whose duty it is to guard the purity of the food and water supply and to control communicable diseases to the end that they may be confined to the household in which they occur. He said that the lives and health of the people were a city, State or nation's greatest asset, and money expended for their conservation is a most economical proposition.

THE YAWP OF A TYPHOID PATIENT.

"Get Well"
Oh! Hell
How can you
When you're blue
And you'd be too,
All day
Far away
On second floor
With shut door.
Oh! my,
Guess I'll die
To-night
For Spite.
The doctor said,
'Keep her in bed
And quiet
Her diet
Milk and broth.'
By my troth
Sorry dishes,
Ye gods and fishes
I'm hungry too
What must I do?
But to be fair
I've had good care,
My nurse there
Would be a loss,
But she's cross.
And I am too, see,
Say wouldn't you be?
But no knell for me
I'll get well
Oh! Hell.

G. H.

One of our correspondents recently interviewed Dr. C. W. P. Brock, the Chief Surgeon of the Chesapeake & Ohio Railroad, in Richmond, and has sent us the following statement, made by Dr. Brock as to the method of

vaccination of the Confederate army. It is of special interest in Kentucky where the State Board of Health has already recommended that vaccination be made with humanized virus where it is possible:

"Richmond, Va., November 18th, 1911.—During the late war between the States, I was sent for by Surgeon General S. P. Moore, and was told that small-pox was very extensive among the Confederate soldiers, and that he wished enough vaccine virus created and collected to vaccinate all the soldiers in the Confederate Army, and this done very speedily; and that he would order as many Surgeons to report to me for duty as I may desire. I asked him how many soldiers were to be vaccinated and he told me two hundred and fifty thousand.

"I asked Rr. Moore to order Dr. Russell Murdock to report to me for this duty. Dr. Murdock reported to me, and I instructed him to commence at the western end of the town and vaccinate all healthy children of healthy parents, and told him that I would do the same thing in the Eastern section of the town, making a house to house visitation. We went to work and vaccinated healthy children under three years of age in six places on each arm, thus securing twelve healthy vaccine crusts.

"At the end of six weeks I had accomplished it, and furnished the Surgeon General for distribution to the Army, healthy vaccine crusts which were distributed, each crust being wrapped in a piece of tinfoil, with instructions how to use it; and in six weeks I had filled the bill, and was complimented by the Surgeon General upon my work.

"In no case was any other disease communicated by the vaccination, and I was successful in stamping out small-pox in the army."

Coley's Toxins in Sarcoma.—Oliver cites ten cases in which he used the toxins, but he had such poor results that he discourages further use. He says comparatively few persons are cured by its administration, the vast majority, at least 90 per cent. of the cases, are uninfluenced by its use. He says one is not justified in assuming that this treatment will ever influence any large proportion of the cases of sarcoma favorably.

Massage of the Nerves.—Joffe relates experimental research which demonstrated a markedly injurious action on nerve tissue from pressure such as is applied in the modern "pressure massage" treatment of neuralgia. Fifty-two experiments showed that the benefit in neuralgia is due to blocking of certain of the nerve fibres from degenerative processes. The centrifugal fibers seemed to suffer more than the centripetal.

COUNTY SOCIETY REPORTS

Boone—The Boone County Medical Society met with Dr. Hafer, of Florence, February, 1912.

After the regular business session, supper was served, after which the program of the evening was taken up.

Gordon F. McKim, of Cincinnati, discussed "Chronic Prostatitis," which discussion was made very interesting with the exhibition of specimens.

W. E. Senour, of Bellevue, who was elected honorary member of our society at this meeting, read a most interesting paper on "Animal Experimentation; Its Contribution to Medicine and Surgery."

After a free discussion of the above subjects the meeting adjourned, to meet the 21st of February with Drs. Langdale and McKim, of Cincinnati.

F. L. PEDDICORD, Secretary.

Bourbon—The Bourbon County Medical Society held its regular monthly meeting Thursday, February 15th, in the Bourbon County Court House at 7:30 p. m.

PROGRAM

Report of Committees.

E. O. Smith, Cincinnati, read a paper on "Relation of Kidney Activity to Surgical Operations."

Dudley Webb, Cincinnati, read a paper on "Specific Urethritis."

Guests from Cynthiaana and Lexington were present. After the meeting a buffet luncheon was served in the basement.

D. B. ANDERSON, Secretary.

Carlisle—The Carlisle County Medical Society met at Arlington in the office of Dr. Jackson, on January 2, 1912, with President T. J. Marshall presiding.

After Divine invocation by Dr. Hocker, the minutes of the December meeting were read and approved.

The Chair appointed as a Committee on Necrology Drs. Hocker, Gholson and Mosby.

The scientific program was next taken up, and consisted first, of an excellent paper on "Broncho-Pneumonia," by **R. T. Hocker**. He covered the field completely.

The next subject was "Lobar Pneumonia," by **T. L. Lamkin**. He, failing to get a program, did not prepare his paper, but made a very interesting and instructive talk.

Both subjects were discussed jointly.

T. L. Lamkin uses veratrum heroically, pushing it for the full effect.

W. Z. Jackson was partial to carbonate of creosote, which, he believes, is almost a specific.

T. J. Marshall and **J. T. Dunn** also took part

in the discussion which was closed by **R. T. Hocker**.

The society adjourned for dinner.

Reassembled at 1:30, and were entertained by Prof. Puckett, of the Arlington High School, who read a very interesting paper on "Medical Inspection of Common Schools." He stated that adenoids and hypertrophied tonsils were causes of dull pupils. Bad teeth should be looked after and in fact all abnormalities should be looked after and corrected.

Every one present took an active part in the discussion. The society regretted very much that the laity was not present to get the benefit of the much needed information. Prof. Puckett closed the discussion.

Members present: Drs. T. L. Lamkin, T. J. Marshall, W. Z. Jackson, R. T. Hocker and J. F. Dunn. Jno. R. Owen, of Arlington, being physically disabled, was absent. Emmet Owen, of St. Louis, being present, was elected honorary member.

The society adjourned to meet at Bardwell on February 6th.

J. F. DUNN, Secretary.

Henry—The Henry County Medical Society met in the office of the Secretary on Monday, January 29th, at 2 p. m. Meeting was called to order by Alfred Wainseott, president, the following members being present: O. P. Chapman, Webb Suter, Everett Morris, A. P. Dowden, W. L. Nuttall and Owen Carroll.

On motion of Everett Morris, the society adopted resolutions congratulating J. N. McCormack and the members of the State Board of Health on the manner in which they have made use of the appropriation made by the last legislature and the direct benefits that Kentuckians are now receiving from the expenditure; endorsing the present system of selecting the members of the State Board of Health and the untiring work of its Secretary. Also the scientific efforts of Dr. South and her collaborators.

Copies of these resolutions are published in full in our county papers and the Courier-Journal. On motion of Everett Morris, the President appointed the following committee to confer with our present Senator and Representative in regard to medical legislation: Everett Morris, W. L. Nuttall and Owen Carroll.

On motion of Dr. Dowden, the following committee was appointed to prepare resolutions in regard to F. J. Yager, the oldest member of the society, recently deceased. Committee: A. P. Dowden and Webb Suter.

The society having decided to prepare a program for its work for the entire year, the Secretary presented the following program, having appointed two doctors to prepare papers for each meeting and two to discuss same.

The society discussed the plan of preparing an operating room at its headquarters for such oper-

ations as may be brought before the society, the plan met with the approval of the members present and will probably be adopted.

A. G. Eliston and W. B. Oldham were elected to membership.

Drs. Suter, Chapman, Waincott, Dowden, Nuttall, Morris and the Secretary, were appointed as a committee to visit all doctors in the county who are not members of the society and endeavor to convince them that they should be members, for their good and the good of the society.

Meeting adjourned to meet again February 26th.

OWEN CARROLL, Secretary.

Henderson—The Henderson County Medical Society met at the Y. M. C. A. building, at 8 o'clock p. m., with President J. W. Cooper in the chair. Others present were, Drs. Forwood, Floyd, Dixon, Branson, Quinn, Letcher, Moseley, Hancock, Neel, Ligon, Griffin, Galloway, Graham, visiting, Drs. Lorton and Wachenfeld. Minutes of meeting December 11th, 1911, read and approved. Motion made and carried to accept program for the year 1912 as printed, committee to make any changes agreeable to, or requested by individual members. Motion made and carried to refer insurance fee matter of Dr. Forwood to a special committee. Motion made and carried that this committee be a special board of censors. The chair appointed the following as said committee: Drs. Letcher, Neel, Galloway. Motion made and carried that said committee report at an adjourned meeting of this society on Monday evening, at 8 o'clock, January 29th, 1912.

A. Dixon read a paper on "Atypical Scarlet Fever." The essayist emphasized the importance of a guarded diagnosis in such cases, easy to diagnose typical cases, but hard to diagnose atypical cases. He thought the most contagious cases should be quarantined.

Discussion led by Dr. Griffin in which he raised the question of proper fumigation after scarlet fever, citing a case where new cases developed in the family ten days after fumigation.

W. V. Neel heartily endorsed the paper, never knew of cases developing after fumigation.

J. C. Moseley thought most contagious stage was when disease was most active. Urged caution in atypical cases.

C. B. Graham spoke of fumigation.

W. M. Floyd enjoyed paper, and spoke of the combining of formaldehyde with permanganate of potash, said some claimed the combination was inert.

W. S. Galloway agreed with the essayist Has had over two hundred cases in the past few years.

E. Branson: Atypical cases are hard to diagnose, urged caution, and isolation.

J. C. Moseley: Does not believe the combination of formaldehyde and permanganate are inert.

A. Dixon, in closing, said he did not believe the combination of formaldehyde and permanganate were inert. He admitted his inability to diagnose atypical cases, an admission in earlier days of his professional career he was not free to confess. The paper was a most excellent one, and timely.

The newly elected President, **James W. Cooper**, read a paper on the "Complications of Influenza." The essayist first told what it was, and then recited the most frequent complications, among which he mentioned pneumonia, bronchitis, tuberculosis, various brain diseases, mentioning the fact that the poison frequently attacked the heart and kidneys. Germs may enter through the respiratory, or alimentary tract. The death rate is 1 per cent.

Arch Dixon, in discussion, complimented the essayist's description of the disease. He thought the disease not near so common as reported. Indicated that when physicians were in doubt they took refuge under the broad term la grippe. He thinks it a very serious disease, giving personal contact as evidence. Said he was benefited by sea voyage. He mentioned the very prevalent practice of giving whiskey in these cases, to the patients' delight, perhaps prolonging his real or supposed indisposition.

J. C. Moseley thought that the complications may be due to the primary cause (grip germ). Complications more really a part of the original disease.

W. S. Galloway thought the disease local at first.

M. V. Neel thought the paper one of the best ever read at this society.

W. M. Floyd said that head symptoms were usually prominent, and urged the importance of giving strict attention to the naso-pharynx, urging thorough cleanliness of these parts.

J. W. Cooper, in closing, referred to very satisfactory treatment by quinine and the coal-tar preparations, stating that to these the disease usually responded very readily.

Our annual banquet was held January 8th, and notwithstanding the very cold weather, there were fifteen present. A splendid feast was served by Parquy, after which came the usual after-dinner oratory, heard only in medical assemblies. The outlook for a splendid year's work by the Henderson County Medical Society is very promising.

PEYTON LIGON, Secretary.

Laurel—The Laurel County Medical Society met in O. D. Brock's office, February 7th, 1912, when the following officers were installed for the year 1912: H. S. Pitman, President; J. B. Mason, Vice President; O. D. Brock, Secretary.

The society is protesting against the passage of the optometry bill.

Next meeting March 20, 1912.

O. D. BROCK, Secretary.

Owen—The regular monthly meeting of the Owen County Medical Society was held in the I. O. O. F. building in Owenton, on Thursday, February 1, 1912, with President Maurice Bell in the chair, and with Maurice Bell, J. W. Botts, A. E. Threlkeld, W. B. Salin, J. H. Chrisman and George Purdy answering present.

The forenoon was devoted to a discussion of "Appendicitis." **A. E. Threlkeld** reported a case. Much interest was manifested in the question of a white blood count being one of the factors in determining whether or not to operate.

W. B. Salin read a paper on "Intestinal Obstruction," which was complimented and discussed by all present.

Two of the essayists begged further time which was granted, and another subject was added making the program for the next meeting as follows: "Heart Murmurs; their Significance and Diagnostic Value," paper: J. W. Botts; discussion: K. S. McBea. "Scarlet Fever," paper: J. H. Chrisman; discussion: R. H. Alexander. "Pellagra," paper: A. E. Threlkeld; discussion: W. E. Foster.

Adjourned to March 7, 1912.

GEORGE PURDY, Secretary.

Pendleton—The Pendleton County Medical Society met at the office of John E. Wilson, at Butler, on Wednesday, February 14th, 1912, with the following members present: Beckett, Blackerby, Caldwell, Clark, Daugherty, Hopkins, Kenball, McKenney, John E. Wilson, J. Ed Wilson, W. H. Yelton.

The meeting was called to order by President Blackerby, and after the usual routine we proceeded to business under new business.

H. C. Clark moved that the State Society be asked to nominate J. H. Barbour as an honorary member of the State Association, on account of his age, eighty-eight years. Motion carried.

On motion of **H. C. Clark** that the chair appoint a committee to draft suitable resolutions indorsing the actions and the course of Dr. J. N. McCormack as a member of the State Board of Health, and pledging him our hearty approval and cooperation, and that a copy be sent to our Senator and Representative. Motion carried.

On motion of **Ed Wilson**, that we as a society draft resolutions in regard to the Vital Statistics Law, indorsing it and ask our Senator and Representative to stand by it. Motion carried.

The following members were appointed on both committees:

John E. Wilson, J. Ed Wilson, C. H. Kendall.

We then had a report of clinical cases, and owing to the physicians all being busy, we only had two papers, which were very good, and brought out free discussion.

W. A. MCKENNEY, Secretary.

Pendleton—The Pendleton County Medical Society met at the office of John E. Wilson, at Butler, on Wednesday, January 24, 1912, this being a called meeting of the society on account of a failure to have our regular meeting on the second Wednesday in the month, due to the inclemency of the weather. The following members were present: Beckett, Caldwell, Daugherty, Hopkins, Kendall, McKenney, Nickols, John E. Wilson, Woolley, W. H. Yelton, visiting, L. F. Poe. The meeting was called to order by Vice President O. W. Brown, and after roll call and a reading of the minutes we proceeded to the business of the day.

Under new business, the Secretary-Treasurer made his report for the past year. The following members paid their dues: O. W. Brown, C. H. Kendall, J. F. Daugherty. We then had a report of clinical cases, and as the members had had a number of interesting cases of appendicitis, the day was spent in reporting the various experiences and a most interesting class of cases was reported. The hour being late, and only one member present with a paper, we decided to hold that over until our next regular meeting, so as to have a full program for that ray.

W. A. MCKENNEY, Secretary.

Rowan—The Rowan County Medical Society met at the office of A. L. Blair, on the 24th of January, 1912; present: F. M. Carter, F. M. Thomas, A. L. Blair, J. Wilson, and G. C. Nickell. The meeting was called to order by A. L. Blair, Vice President, and upon motion G. C. Nickell, Secretary, read the minutes of the last meeting. On motion of F. M. Carter the minutes were unanimously accepted.

On motion of J. Wilson, and seconded by F. M. Thomas, that all former medical societies existing in Rowan county be dissolved and held as void, and for the members present to organize what shall hereafter be known as the Rowan County Medical Society, the motion was unanimously adopted by all members present.

On motion of F. M. Carter, and seconded by J. Wilson, that the members proceed at once to organize, this motion received the unanimous vote of all present. The Chairman having declared nominations now in order, whereupon F. M. Carter nominated F. M. Thomas for President, which was duly seconded, and there being no other nominations, Dr. Thomas was elected by acclamation.

On motion of J. Wilson, and seconded by G. C. Nickell, A. L. Blair was put in nomination for Vice President; there being no other nominations, Dr. Blair was elected by acclamation.

On motion of F. M. Carter, and seconded by F. M. Thomas, G. C. Nickell was nominated for Secretary, and there being no other nominations, G. C. Nickell was elected by unanimous vote.

On motion of J. Wilson, and seconded by F.

M. Thomas, G. C. Nickell, F. M. Carter and A. L. Blair were elected Censors.

On motion of F. M. Carter, and seconded by G. C. Nickell, it was moved that the next meeting be held in the courthouse on Friday, February 23rd, 1912. Said motion carried unanimously.

On motion of F. M. Carter, and seconded by J. Wilson, the society voted to adjourn.

G. C. NICKELL, Secretary.

Spencer—The Spencer County Medical Society met at Dr. Crenshaw's office on Monday, January 15th, at 3 o'clock P. M. Our county being small, it necessarily follows that our society is small; we have ten physicians in active practice, six of this number being members of the county society.

The meeting was called to order by Vice President E. C. Wood and after hearing the Secretary's report, the election of officers was taken up: E. C. Wood was elected President; B. F. Shields, Vice President; O. M. Crenshaw, Secretary-Treasurer; S. L. Reid, Censor; J. F. Furnish, Delegate, and R. Y. Shepherd, Alternate.

The Secretary was ordered to write the members of the legislature from this county, asking them to use their influence against any proposed legislation licensing any one to fit glasses, or in any other manner treat diseases of the eye, except regularly qualified doctors of medicine.

The Secretary was also instructed to write the Secretary of the State Board of Health and ask him to appoint Doctor E. C. Wood, J. F. Furnish, and O. M. Crenshaw as members of the county board of health.

Several matters of local interest were discussed; each member present renewed his allegiance to the State Association by depositing with the Treasurer \$2.50 and expressed a heartfelt desire to save the county society from dissolution and pledged themselves to attend the meetings and do what they could to support the society and help each other.

R. Y. Shepherd very kindly invited the society to meet with him at the next regular session; invitation accepted.

O. M. CRENSHAW, Secretary.

Warren—The regular annual meeting of the Warren County Medical Society was held at St. Joseph's Hospital, Wednesday, December 13th. J. W. Lewis in the chair, and the following members present: F. D. Cartwright, H. P. Cartwright, W. P. Drake, F. G. Rogers, E. N. Hall, W. J. Keen, Finis London, B. S. Rutherford, I. H. South, W. F. Arnold, J. N. McCormack, J. H. Blackburn, T. W. Stone, W. C. Simmons, J. W. Lewis.

E. J. Keen reported some unusual cases. The first, a normal delivery, one hour after birth of child patient had syncope, became pulseless, unconscious, uterus firmly contracted. In two hours patient rallied and made an uneventful re-

covery. No apparent reason for the untoward symptoms. Case 2. Man lived fourteen miles in the country, age 28 years, unmarried. On the previous evening ate a large amount of pickles, salmon and crackers, had convulsions, was unconscious, urine showed presence of large quantity of albumen. Died in two days. Never regained consciousness. Case 3. Baby born without anus. Operated, found the rectum only a small cord. Baby lived one week. Case 4. Negro, sixteen years old, during a fight his opponent stuck a knife into the skull which broke off. The piece could not be removed with all kinds of forceps, so trephined into the skull and recovered the portion of blade.

H. P. Cartwright discussed the cases and reported several that had occurred during his long years of practice.

L. H. South gave a stereopticon demonstration of hookworm infection in Kentucky.

W. F. Arnold outlined the treatment.

The following officers were elected: President, T. O. Helm; Vice President, Finis London, Woodburn; Second Vice President, W. P. Drake; Delegates, W. C. Simmons, H. P. Cartwright, B. S. Rutherford; Alternae Delegates, Finis London, W. P. Drake, J. N. McCormack; Sensors, T. W. Stone, J. G. Rogers, E. J. Keen.

L. H. SOUTH, Secretary.

Warren—The regular meeting of the Warren County Medical Society was held at St. Joseph's Hospital, January 10, 112, at one p. m., with the following doctors present: W. F. Arnold, J. H. Blackburn, W. P. Drake, L. H. South, T. W. Stone, A. T. McCormack, H. P. Cartwright, Reardon.

H. P. Cartwright read a paper on "Prognosis of Pneumonia," a specific disease, specific cause, runs its course in a limited time if we do not do too much for it. Lobar pneumonia in infancy rarely kills, runs a typical course, temperature usually runs high. Rarely a death unless due to complication. Formerly they were bled, given aconite, fresh air, warm room, pain rare, never blister. Treatment. Essentially for comfort of patient, opiate if necessary. Warm, moist atmosphere. Use purgative, calomel especially. Dry harsh cough, alkaline carbonates. Ammonia carbonate, Dover's powder. Coal tar products for high temperature. No complications can predict favorable results. Strychnine for stimulants. Does not give digitalis. Just before crisis symptoms unfavorable. Gaseous fermentation frequent occurrence in pneumonia.

W. F. Arnold saw a great deal of pneumonia during student days. Saw epidemic of pneumonia on ship. Showing effects of cold draughts on etiology of pneumonia. Reduced vitality caused pneumonia, chill practically at night. Treated one hundred and fifty cases. In central pneumonia diagnosis difficult until rusty sputum occurred. Saw very virulent pneumonia among In-

dians in Alaska. Mortality very high. Mortality not great in the young. In Chinese and Japanese war, never recalled a case among them. Cuban soldiers, saw a great deal of pneumonia, lobar pneumonia very fatal in the aged. Father had it followed by abscess of lung, (eighty years old).

J. H. Blackburn: Negro woman beyond eighty lobar pneumonia, recovered. Patient seventy-nine. Condition at present not favorable. Alcoholism deleterious effect on pneumonia patient.

E. N. Hall called last night to see a man with pneumonia. 104 P. 126, age 26 years. Called next morning, patient's temperature normal.

A. T. McCormack gave report of Vital Statistics in which 8 per cent of deaths were due to pneumonia.

F. D. Reardon: Man, age 83, lobar pneumonia, recovered. Died three years later of kidney trouble. Father died of pneumonia. He advocated bleeding.

L. H. SOUTH, Secretary.

Warren—The regular meeting of the Warren County Medical Society was held at St. Joseph's Hospital, Wednesday, February 14th, 1912. T. O. Helm, the president, in the chair and the following doctors were present: W. P. Drake, Moss, Lewis, Arnold, Adair, Richard Drake, Souther, Huddle, London, Rodgers, Blackburn, Briggs, McCormack, Helm, South, Weaver, of Allen Springs; Cartwright and Hall.

W. F. Arnold gave the report of the committee on selection of place of meeting.

The Mayor **Dr. G. E. Townsend**, offered a room in the City Hall which was accepted by the society.

W. F. Arnold moved the society appoint a Committee on Library. The president appointed W. F. Arnold, J. H. Blackburn and J. W. Lewis.

J. H. Blackburn donated a complete file of the Kentucky Medical Journal.

A. T. McCormack offered files of the A. M. A. Journal and some recent works on Surgery.

A. T. McCormack spoke on the "Operative Treatment of Fractures."

W. F. Arnold lengthily discussed the subject.

G. E. Huddle reported a case of gun-shot wound of the arm.

J. H. Blackburn spoke of his recent visit to Philadelphia attending the Surgical Association.

W. A. Briggs reported a case where the patient fell out of a tobacco barn injuring the fibula, a large lacerated infected wound resulted so that a portion of the fibula had to be removed. The patient has excellent use of the ankle.

A. T. McCormack reported a case of interval appendectomy. The appendix was buried in a sac of adhesions back of the colon, the appendix was large and funnel shape, and was removed with a great deal of difficulty.

Finis London proposed the time of meeting be changed from 1 p. m., to 10 a. m. It was decided

that the Secretary notify all members and ask them to vote on this question.

J. H. Blackburn reminded the society that the April meeting would be held here in conjunction with the Logan and Simpson County Medical Societies.

The society adjourned to meet March 13,
L. H. SOUTH, Secretary.

Warren—A call meeting of the Warren County Medical Society was held Saturday, January 20, 1912. The meeting was called to order by Vice President W. P. Drake.

J. H. Blackburn told in detail that the meeting was called for the purpose of sending a resolution to our Representative and senator requesting that they vote against House Bills numbers 90 and 74, and also that the Vital Statistics Law remain intact.

W. F. Arnold, F. D. Reardon, J. H. Blackburn, T. W. Stone, E. N. Hall were appointed on the committee and wrote appropriate resolutions and sent them to our representative and senator.

No other business the society adjourned.

L. H. SOUTH, Secretary.

Whitley—The Whitley County Medical Society met in Williamsburg, February 1st. President S. S. Brown presiding. Members present. S. S. Brown, A. A. Richardson, J. E. Ellis, L. B. S. Brown, A. A. Richardson, J. E. Ellis, L. B. Croley, L. O. Smith, A. T. Slemmons, J. H. Parker, T. J. Ballard, E. S., and C. A. Moss, P. G. Petrev, G. G. Ellison and M. W. Steele.

At the invitation of the society **Dr. J. J. Moren**, of Louisville, was present with a paper on "Acute Spinal Paralysis." The paper of Dr. Moren, which will appear in the JOURNAL, was a masterpiece on the subject, and brought forth many words of praise and commendation from all present. Those discussing the paper were **E. S. Moss, T. J. Ballard, L. B. Croley, J. H. Parker and L. O. Smith**.

J. J. Moren fears a general epidemic.

J. H. Parker read an excellent paper on "Cerebro-Spinal Paralysis." This paper will be published in the JOURNAL.

L. O. Smith, L. B. Croley, E. A. Moss, J. J. Moren, S. S. Brown, C. A. Moss, A. T. Slemmons and L. O. Smith lead in the discussion.

All cases reported showed a very large mortality. **S. S. Brown** reported having treated ten cases with only one recovery. The iodides was the treatment in this case.

A. T. Slemmons thinks well of the serum treatment. **J. H. Parker** has noticed that the largest mortality occurs in females. **J. J. Moren** states that a number of cases have been reported occurring in physicians.

The society was entertained with a splendid dinner at the Gentry Hotel by Dr. E. S. Moss, after which the society reconvened for a short business session.

After some pointed and well taken remarks by the President for the good of the society, **Drs. Lafayette Sproule and Seabury Sullivan**, the oldest practitioners in the county, were voted honorary members of the society for life.

J. H. Parker and L. B. Croley were elected delegate and alternate delegate to the State Association.

A vote of thanks was extended Dr. Moren for his paper, and the Secretary was instructed to enroll him as an honorary member of the society.

The next meeting will be held at Corbin, April 4th.

M. W. STEELE, Secretary.

BOOK REVIEWS

Merck's Manual of the Materia Medica, (Fourth Edition)—A Ready Reference Pocket Book for the Physician and Surgeon. Containing a comprehensive list of chemicals and drugs—not confined to "Merck's" with their synonyms, solubilities, physiological effects, therapeutic uses, doses, incompatibles, antidotes, etc.; a table of therapeutic indications, with interspersed paragraphs on Bedside Diagnosis, and a collection of Prescription Formulas, beginning under the indication "Abortion" and ending with "Yellow Fever"; a Classification of Medicaments; and Miscellany, comprising Poisoning and Its Treatment; and an extensive Dose Table; a chapter on Urinalysis, and various tables, etc. (Merck & Co., 45 Park Place, New York, 1911. 493 pages. Sent on receipt of forwarding charges of 10 cents, in stamps, to physicians, or to students enrolled in any College of Medicine, in the United States).

Injection of Blood Preliminary to Operations.

—Esch refers in particular to extremely anemic and weak patients with hemorrhagic uterine myomas. They need myomectomy at once and yet their resisting powers are at a dangerously low ebb. In order to improve conditions he injected defibrinated blood in two cases; three injections of 20, 15 and 30 c.c. and 15, 20 and 22 c.c. of the defibrinated blood in the course of fourteen days, improving the condition to such an extent that the hysterectomy was then safely performed. The hemoglobin rose from 25 to 46, and from 23 to 36 per cent., the improvement parallel in both cases and evidently strictly connected with the injections.

THE AFTER TREATMENT OF ABDOMINAL OPERATIONS.

By LEWIS S. McMURTRY, Louisville.

On a previous occasion I presented a paper to this society on the subject of complications following abdominal operations, and it has occurred to me that we could profitably consider, this evening, much more briefly than on the preceding occasion, the after treatment of the average abdominal operation, excluding the management of complications and exceptional symptoms.

The interest that pertains to this subject with all of us is obvious, because the after-treatment of abdominal operations often falls into other hands than those of the surgeon who does the operation, and it is frequently a matter which requires the combined services of the physician and surgeon, which facts make the subject one of almost universal interest.

Among the many interesting and instructive object lessons at the World's Fair in Chicago, there was none that was more impressive than that in the Transportation Building, where a replica of the first steam locomotive that was ever used, was put alongside a modern, perfected, Baldwin locomotive of the present time. These two machines looked as if they had no kinship; the evolution of the modern locomotive could scarcely be traced step by step from one to the other, so much did these two machines differ. Yet there stood out one great, important lesson—the principle of locomotion by steam was the same in the one as in the other. Now, I think

it may be appropriate to use this simile to illustrate the evolution of modern surgical technique. Whereas to-day the surgical operation in all its technical details is so different from what it was fifteen years ago, and especially in abdominal surgery, that it seems that the whole thing has changed and left very little of what was there at first; yet, just as the same principle is in the modern locomotive as it was in the first locomotive, so the Listerian principles that underlie surgery are just the same to-day as they were before. But it is a fact that the perfected modern technique in surgery, which has evolved from the early and first methods, has exerted a most wonderful influence over the after treatment of abdominal operations.

You all remember that in the early days we did a great many things that we do not do now. It was absolutely necessary to pass through this period of evolution in order to separate the wheat from the chaff, the essential from the non-essential, to eliminate the things that were harmful, in order to reach that condition which marks perfection in all departments of art, and that is *simplicity*. It is only by the process of evolution that this can ever be done in any department of surgery. As Velpeau expressed it, "Surgery is never so attractive as, when stripped of all its paraphernalia and useless hand-ages, it stands forth in its naked perfection." So, if you take any department of surgery whether it be brain, abdominal, or orthopedic surgery, in the advancement of the work the non-essentials are thrown aside, and perfection is marked by simplicity.

In early times, one of the very first things that embarrassed the after treatment of abdominal operations, was the method of anes-

thesia. I must take up these points in order that I may forcibly present to you the first and essential point in the after treatment of operations, when I state to you that the after-treatment is really fixed at the operating table. This was one of the diets of Mr. Lawson Tait, the founder of modern abdominal surgery, who said that the fate of the patient is determined at the operating table more than anywhere else, and that many errors of diagnosis are reclaimed there. Mr. Greig Smith, in alluding to this observation of Tait, amplifies it, and says that there should be a standard of surgical attainment at the operating table which will leave nothing to chance, and that when the abdomen is closed, the surgeon should know, as far as possible, the exact condition that exists therein, and carry with him from the room a mental picture of it, and complete every detail of the operation in a workmanlike manner. So, if we consider the after-treatment of abdominal operations from the standpoint of operative proficiency that has reached, or at least approached, this standard, we will have an after-treatment that is simple and relieved of many of the embarrassments that formerly existed.

First, I would call attention to the older methods of preparation of the patient, and this is not a reproach to the methods of the previous age, because, as I have endeavored to show in my introductory remarks, there can be no attainment of a system of perfection of any surgical technique unless it has first gone through a process of evolution. It is only by testing all the various methods that we are able to adopt the best and dispense with those which are unnecessary. Some of the gentlemen here will recall the time when it was considered necessary to begin the preparation of the patient a week before operation. The patient was excessively purged, calomel was the favorite means of purgation, and it was not an uncommon thing in emergency operations, for the patient to come to the table with the entire alimentary tract churned up with calomel and salts. Of course, that complicated the after treatment. Now that is all gone. I think another important feature in regard to this point is that we now know that it is absolutely harmful; that the patient should not be depleted by excessive purgation.

Another factor which has a great deal of influence upon the after treatment already mentioned is anesthesia. You will recall the time when the anesthetic was administered often times by the family physician; when the professional anesthetist was unknown, and the patient breathed over and over again the same air. This has all been changed and the condition of the patient's kidneys and other eliminative organs after an operation now,

is altogether different from what it was under the old system.

If we take up the methods of treatment directly in connection with the operation itself, we will find that there has also been marked change. Formerly it was the custom to perform all surface operations under a stream of water, and rarely did we see an abdominal operation, especially if there was a septic condition within the abdominal cavity, where lavage was not used. Wet sponges were also used, as they were considered more efficient for absorption, and water flooded all incisions and surfaces. We now know that lavage over incised tissues carries out of those tissues the elements so essential to the repair of wounds, and by the elimination of lavage, the after treatment of abdominal operations has been improved and simplified as to the wound itself, and as to the repair of traumatisms on the inside of the abdomen. With these conditions observed, it was exceptional that an operation was not followed by shock, the extensive lavage, exposure and scraping of the peritoneum being very potent factors in the production of shock. It is exceptional now, in the average operation, where the hemorrhage is controlled as it can be under modern technique, for the surgeon to have to deal with shock as a post-operative complication.

Under the old methods, just as soon as the patient was put to bed he was deprived of water for three days, and suffered torture. You can all remember the time when, under the old system, just as soon as the patient was put to bed the most conspicuous symptom was a terrific thirst and water was withheld. The pain was severe, and it was considered unwise to use an anodyne, such as 1-8 gr. of morphin, or 1-12 grain of heroin, or 1-4 grain of morphine hypodermically, which we now know is not harmful but is really beneficial in the relief of pain and distress and does not produce intestinal stasis as was formerly believed.

Under the old system, just as soon as the patient was put to bed, the surgeon's attention was immediately addressed to moving the bowels. It was considered that the patient could not be termed convalescent until the bowels had moved, and it was the routine practice by many surgeons of high position and authority to begin, within twenty-four hours, to drop calomel on the tongue, as the one agent that would be retained during the stage of vomiting. They also resorted to so-called high enemata and all possible means to make the bowels move as quickly as possible, and when they did move the patient was considered to be in a fair way to get well. It was deemed the best means of eliminating any infection which might have existed at the time of the operation. Now all this has pass-

ed away. There is no necessity, as we now know, of withholding water from the patient. It is good treatment to give patients water when they can take it, and if they vomit it makes no difference. We know also that there is no reason why the patient should not be given an anodyne, and there is no good reason why we should purge the patient immediately after operation. These are items that, in the process of evolution, have been eliminated as a result of improved knowledge.

Now it is good practice, when the patient has been returned to bed after an abdominal operation, to consider first the question of position. If it is an operation for a septic condition, where a large amount of septic material is retained within the abdominal cavity, the law of gravity should, of course, be utilized for drainage. If the operation is in the upper abdomen, such as operations upon the stomach, gall-bladder, etc., this principle should also be utilized. We know that it does not interfere with the comfort or safety of these patients to place them in the Fowler position and maintain it for some time.

Among other things that have been largely eliminated from abdominal surgery, is drainage. Tubal drainage was formerly employed in the majority of non-septic cases as a matter of safety and precaution. It was considered that, by this means, post-operative hemorrhage could be detected, and elimination was perfected, even though the sepsis was not profound. This has been discarded and, as a result, infected wounds, minor degrees of infection of the peritoneum, injuries to the peritoneal surface and viscera, and especially, infection of the incision, have disappeared from the after-treatment of abdominal operations.

Modern methods of suturing and dressing have done much to eliminate unnecessary details from the after treatment; the use of animal suture material, which in the tissues yields readily, and does not by strangulation produce suppuration in the wound, which condition obtained when strong, silkworm-gut sutures were applied *en masse*, and almost invariably tied too tightly. As the result of interference with the circulation, suppuration occurred, and a stitch-hole abscess developed. As declared in an address by Dr. Senn, it was a rare thing to pass through one single day without meeting a stitch-hole abscess. Now we go for years without such unwelcome result.

In our admiration of the great principles of antisepsis underlying the Listerian system, we often overlook the fact that Lord Lister introduced the animal suture into surgery in the form of catgut, and that absorbable sutures and ligatures are an essen-

tial and important part of the modern system of wound treatment.

All of these things are the result of cumulative experience, study, bacteriological investigation, and the work of surgeons, which has extended our field of knowledge and perfected our methods.

I wish to call especial attention to one thing that I have noticed frequently in recent times, and that is undue solicitude in regard to the bowels moving. It is very exceptional that it is necessary to do anything for the patient in the way of preparatory treatment, except to have them come into the hospital on the day before operation, given a dose of castor oil, and then be prepared for operation. After operation do not give a purgative; give an enema, and if this is not effective, give another enema, and if these are not effective, then, perhaps, on the fourth or fifth day, give a dose of castor oil or some other laxative preparation.

Our knowledge as it has increased has shown us that keeping patients in bed for a long time is detrimental to their welfare, and that just as soon as the healing process is established, especially if the patient is over the effects of the anesthetic and the digestive and eliminative functions have been resumed, we can allow them to get up to the comfort and move the bowels without any risk, after the average abdominal operation, and that it is unnecessary to keep them in bed for a long time, and especially is this true of older patients.

Medication of patients after the ordinary abdominal operation, should be avoided. Feeding should be begun as promptly as possible, and the patient should be returned to a regimen very much like that of a patient convalescent from any other condition, without impairing the digestive function, and, on the other hand, without restricting them to the point of depletion. Especially is this important in cases where there has been a great deal of hemorrhage. The use of tonics is rarely advantageous in these cases. The days of excessive medication and unnecessary interference has passed, and we now endeavor to secure a return to normal conditions as soon as possible, enabling the patient to be up and about at an early date, and getting them out of the hospital in a reasonably short time. Much of the advantage of modern after-treatment is due to the fact that patients now come to operation earlier than before. Surgery has "made good" in the eyes of the profession, and operations which were formerly done only as a *dernier resort*, are now performed early, and, of course, the after treatment of these cases is much simpler now than formerly.

I have not undertaken to treat the complications that follow exceptional cases, but it

has been by endeavor this evening to call your attention to the after treatment of the average abdominal operation, and to present to you the general principles of after-treatment which can be modified to meet special conditions as may be necessary. As a rule the treatment is simple, and requires neither medication nor repeated dressings.

DISCUSSION.

J. G. Sherrill: This is a subject that is of interest to all of us, especially because we have all seen the changes that Dr. McMurtry mentioned, in the treatment of wounds, particularly abdominal wounds. I can recall the time when drainage was employed in almost every abdominal section, first with glass tubes and later with rubber tubes, with a wick inside. Finally we learned that we could dispense with drainage even in pus cases. I think it was John G. Clark who first made the claim that we were employing drainage too frequently, and his statement excited quite a lot of discussion. Finally, however, the profession came to realize that he was largely right.

I agree with Dr. McMurtry in regard to the old methods of preparation of the patient, by purging, etc. I like to give a laxative two days before the operation and let the patient alone on the day before. In that way the stomach is less likely to be disturbed and the patient is less apt to have nausea and vomiting occur, however, I have never found anything to equal washing out the stomach. Sometimes once will be enough; other cases will require two washings.

I believe in the early feeding of patients. A member of this society recently made a very brilliant report of a double resection of the intestine, in which he did not feed the patient for nine days, which is much longer than I think it necessary to withhold food. It is the custom now to begin feeding much earlier than we formerly did.

I wish to emphasize the fact that these patients will do a great deal better when placed in an elevated position in bed. This position seems to give the patient more encouragement than the fixed position on the back in which we formerly kept them.

I can recall the time when we used to have stitch abscesses, and remember the improvements that were made, step by step, in this respect. For instance, it was suggested by some that scrubbing the abdomen did severe damage to the cells, diminishing their resistance and thereby allowing infectious material to grow more rapidly. When that was stopped and we simply washed the abdomen with soap and water with soft gauze and alcohol, we found that there was less suppuration. Then when we began to employ rubber gloves, there was still less suppuration. Occasionally, however, wound infection would occur, and when we learned that the atmosphere breathed by the surgeon and his assistants con-

tained a great number of bacteria, we understood the source of these infections. When the mask was adopted, entirely excluding from the field of operation the faces of the surgeon and his assistants, wound suppuration disappeared, and now it is the exception for a clean wound to show any suppuration whatever. Generally, when a wound is clean from the start, the patient is out of bed in ten days, whereas we formerly had to keep them in bed three or four weeks.

Like Dr. McMurtry, I am very much opposed to strenuous efforts to move the bowel after operation. It is much better to put a tube into the rectum to let the gas out, and then, on the third, fourth or fifth day, give an enema and depend upon Nature to do the rest.

Wm. H. Wathen: Dr. McMurtry has presented such a correct review of the evolution from our early abdominal surgery to the perfection of to-day, that it leaves but little for any of us to add. I went through the early evolution, when we had no nurses and had to sterilize our own paraphernalia, and I have watched all the steps of advancement. To-day when I complete an operation and return the patient to bed, I think but little more about the case until I see the patient the next day. I have not been called to St. Anthony's hospital where I usually operate after I had retired at night, a single time in the past six years, whereas, fifteen or twenty years ago, I was called out about every other night. When I have completed my work I know that the patients will get well, under good nursing, about as well if I never see them again.

One of the great things that we have learned is to commit as little traumatism as possible in abdominal work. This is largely the secret of our success. No good surgeon of to-day would use lavage in the abdominal cavity, even in pus cases. It does no good, so far as washing away the infection is concerned, and we may wash away a good deal of pus filled with healthy phagocytes. By lavage, even if we do not sponge out the cavity, we commit traumatism upon the epithelial cells, weakening their power of resistance and their ability to take care of the deeper structures and prevent the absorption of bacteria into the system.

We have also learned that we must expose the intestines just as little as possible. Hence, when we operate, we commit no traumatism, and we sponge as little as possible, and this, together with elevation of the patient to facilitate drainage by gravity, marks a great change from former methods. If septic material is allowed to remain in the region of the diaphragm in the upper abdominal cavity, the germs will be rapidly absorbed into the system after having done great damage in the peritoneal cavity. If, on the other hand, these patients are elevated so that the septic material will drain down into the pelvis, where absorption does not occur so readily, and from which cavity, if need be, we can drain the

material with a rubber tube or a wick, they will nearly all recover. Under the old methods, nearly all cases of extensive suppurative peritonitis, and practically all cases of diffuse suppurative peritonitis, died. Under the present technique, committing as little trauma as possible during the operation, elevating the patient and draining from the bottom of the pelvis, practically all of them get well.

Another advance, not mentioned by the essayist, is the use of saline injections—proctoclysis. With our patient elevated so that the septic matter in the cavity will drain down into the bottom of the pelvis, if we will introduce into the rectum by the drop process, warm saline, so as to fill the bowel and system with water and thus flush out the kidneys, we will find that a patient suffering with appendicitis, or with almost any other infection within the peritoneal cavity, will get well. Of course, there are exceptions, but we now have few deaths following operations for appendicitis, or for other forms of infection in the abdominal cavity, if we get the patient before too much damage has been done.

Edward Spidel: I have enjoyed Dr. McMurtry's paper very much indeed, especially since I have had the pleasure of seeing these evolutions in surgery. The essayist's remarks as to the extensive preparation formerly made, and especially in regard to lavage, reminds me of a paper presented by a New York surgeon at the first meeting of the Society of Obstetricians and Gynecologists in this city, ten years ago. In this paper the essayist gave an account of an operation performed upon a very wealthy woman of New York, in which the surgeons took every precaution known to surgery at that time in order to insure a perfect result. One method in vogue at that time was suturing through and through with silk-worm gut, which was done in the case reported, and the essayist stated that, upon removing the sutures on the ninth day, it was found that the entire wound remained open, and he said he believed this was due to too much asepsis—too much care in preparing the wound, and that better union would have occurred if so much of the products of Nature had not been removed.

The after treatment of operated cases should, of course, begin just as soon as the anesthesia stops, and the anesthetist should perform part of that treatment. I believe it is the custom, in this city, to administer oxygen gas after the anesthesia has been stopped. In the East, in a number of hospitals, it is the practice, after operation, to carefully cover the patients with blankets and wheel them out into the open air, no matter what the weather is, allowing them to breathe the fresh air and thus get rid of the ether retained in the bronchi. I should think this would aid in the quick recovery of the patient and lessen post-operative vomiting.

It was also the custom in former years to keep the patient upon the back for forty-eight hours,

allowing no change of position at all. Now, in ordinary cases, it is the practice to turn the patient upon the side as soon as they become uncomfortable.

In regard to feeding, in former years, after the first two or three days, water was given in minute quantities, and then after a few days broths were allowed, and so on. Now, of course, this has all been changed and there are some extremists who give their patients any kind of food desired on the second or third day.

In regard to getting the patient up early after operation, there seems to be two extremes in this respect; some surgeons permit their patients to get out of bed on the second or third day, while others keep them in bed for a much longer time.

Hugh N. Leavell: I have very much enjoyed Dr. McMurtry's expose of this subject.

I agree with Dr. McMurtry and other speakers that discontinuance of former methods of preparation of patients certainly obviates the necessity for long continued after treatment. When the bowel is over-exerted by so much purgation before operation, it becomes a ready prey to typhoid. This is really not a complication of the operation, nor does it signify impending peritonitis, but I think one of the chief reasons we have it is long continued purgation prior to the operation.

I remember that, some fifteen years ago, it was the common practice at all infirmaries, to keep an hypodermic syringe loaded with nitroglycerin and strychnia, and this was administered in nearly every case. We know now that this facilitated and hastened the production of shock in many instances. I am sure that no infirmary at the present time would use such a combination. In former times it did a great deal of damage that is not now done, because all the surgeons are preaching simpler methods, just as the physicians are coming closer and closer to Nature in the treatment of disease. Simplicity seems to be the keynote of Dr. McMurtry's paper, and I believe if we will all try to follow more closely the laws of Nature, we will get better results.

J. Hunter Peak: I have very much enjoyed Dr. McMurtry's talk on this subject. I have noted in my own experience, one point that the essayist brought out; namely, that the trend in all scientific inventions and surgical procedures is towards simplicity. I believe we all recognize the fact that a great deal of preparation prior to operation has an influence on the patient's mind, leading them to expect everything and anything that is bad, and this has a direct influence upon the after treatment. I am in the habit of being cheerful in the presence of my patient, and talking about everything but the operation. I do not mention the operation at all, except possibly to say that it is a simple matter and that they need not worry about it. If we can influence our patients' minds in this way, it will have a great deal to do with the after treatment.

I agree with Dr. McMurtry that the preparation of the patient should be as simple as possible. I make it a routine practice to send the patient to the infirmary the day before operation, give a dose of castor oil and instruct the patient to drink all the water they want up to midnight, and then operate early the next morning. They are permitted to have water as soon as they desire it after the operation. I do not think it is necessary to compel these patients to take hot water. If a patient is thirsty and vomiting, it is a very good practice, unless there is some contraindication, to give them a small amount of saline per rectum, sometimes before they leave the operating table. It will prevent thirst from coming on so early. If the vomiting continues and the patient is not able to retain liquids, the thirst can be relieved in that way at any time.

I remember the time when it was considered essential for the patient's bowels to move not later than the second day after operation. That is not considered necessary now unless the patient complains of distension, and then we can instruct the nurse to either introduce a rectal tube to let the gas pass off, or to give an enema, using just enough water to stimulate the bowel and cause it to empty itself, after which the patient will feel perfectly comfortable.

In regard to feeding, I believe that we formerly did many of our patients a great deal of harm by feeding them meat juices, soups, broth, milk, etc. When we take a person off his feet and put him to bed, he does not need much to eat, because there is not much waste, and the thing to do, if we do feed them, is to give them something they are in the habit of eating; food that will give the alimentary tract something to do. In my opinion, however, most patients, after a major operation, will do very well if they are not fed anything for forty-eight hours; they really do not care to eat. Digestion is impaired anyway because there is a good deal of nervous shock, not surgical shock, because we rarely ever have a condition of that kind now for the reason that we now know how to give the anesthetic and how to operate so as to get the patient off the table in the shortest possible time. Furthermore, anesthetists have learned how to keep the patient under surgical anesthesia without giving them too much of the anesthetic.

I think the point brought out by Dr. Speidel, in regard to plenty of fresh air following the administration of an anesthetic, is a very good one. It is our practice to put these patients to bed close to an open window, keeping them wrapped up warmly, and I always tell the anesthetist to give them oxygen before they leave the operating table.

It is a good plan, following an abdominal section, to place pillows beneath the knees, thus relieving the tension on the abdominal wall and stitches therein.

We have also learned that it is not necessary to

tie stitches as tightly as we formerly did; that it is sufficient to simply approximate the tissues. We can use animal suture material throughout, because the sutures will be absorbed quickly, while, on the other hand, silk sutures last too long. In using chromic suture material, we need not use it stronger than No. 1, unless there is some special reason for doing so. We can use No. 1 for all suturing except probably the fascia. In closing the fascia it should be done with No. 1 twenty-day.

Another thing that I think is very beneficial in the after treatment, is a properly fitting bandage. The old style bandage, going all around the body, we discarded many years ago, as well as the old plan of covering the wound with a lot of gauze, thus making the patient uncomfortable. We now use four or five thicknesses of gauze, about two inches in width, to cover the abdominal incision, and then cover and hold it with adhesive plaster, passing well over on the other side. Then, if for any reason we desire to change the dressing, with a pair of scissors we can split the adhesive plaster over the dressing, turn it out and put on a clean one and pin the edges with safety pins. In cases where drainage is necessary we may have to use a bandage.

In regard to position, I believe that changing from one position to another has a very good effect upon the patient's mind. If they do not feel like lying flat on the back, put a pillow under them, or change the position slightly to one side or the other, and thus give them some rest by changing the center of gravity.

Jno. W. Price, Jr.: I have very much enjoyed Mr. McMurtry's paper. The subject of after treatment is one in which we are rapidly making progress. The essayist spoke of using a small amount of drainage now where we formerly used a large quantity. One striking change that I have noticed is that, as a rule, drainage is not left in the wound as long now as it formerly was. When I began my surgical practice some five or six years ago, it was the custom to leave practically all drains in position for seven to ten days; now it is exceptional that a drain is allowed to remain as long as seven days, and in the majority of cases they are removed in 72 hours, or by the fifth day at the latest.

The question of the preparation of the patient with a view to simplifying the after treatment brought to my mind the use of tincture of iodine in preparing the skin, in which I have been very much interested. Recently a German surgeon reported that out of 70 cases of all varieties of appendicitis prepared by this method, he had six cases of post-operative ileus, whereas, in a former series of 300 cases, in which soap, water and alcohol were used in preparing the skin, only three or four cases of post-operative ileus developed. I have been doing some experimental work along this line on dogs. I have under observation at the present time a number of dogs that were op-

erated upon some time ago. They were simply taken from their cages, without any preparation at all, put upon the table, the belly swabbed with tincture of iodine, some abdominal operation done and the wound closed. It is my intention to open up these dogs, after a period of three or four months shall have elapsed, and see whether there are any post-operative adhesions. None of these dogs developed any symptoms of obstruction, but it will be interesting to learn what influence, if any, iodine has in the production of post-operative adhesions.

F. T. Fort: I have enjoyed Dr. McMurtry's paper very much indeed. His comparison of the progress of surgery to the difference between the small locomotive of the early thirties and the large one of the 20th century is, I think, very appropriate. Since I graduated, seventeen years ago, we have abandoned oxalic acid and potassium permanganate for sterile water and alcohol. Before that we used soap and a sponge, and used silk in the abdomen, usually tied too tightly, and often very serious complications resulted. Now we have discarded practically all these things for simpler methods.

There are three things which I think are more important factors in post-operative convalescence than anything else; namely, anesthesia, better preparation of suture material, and the use of rubber gloves. A few years ago, before starting for Europe to take up some post-graduate work, it was the custom to wash out the abdominal cavity with water, and a good many operators were operating without gloves. In Europe I found that they were not only using rubber gloves, but wore masks to keep the respiration from contaminating the wound, furthermore, that they were in the habit of closing the wound without irrigating the cavity with water. About a year after I came back these methods were adopted here, and since we have discarded the use of water our patients do much better.

I think it is essential to have a thoroughly reliable anesthetist, one who understands the shock ratio of different tissues, and how to keep the patient under surgical anesthesia without carrying it to the point where there is more or less profuse narcosis.

If anything is to be given to move the bowels, I believe that an enema, with the addition of a little eserine hypodermically is beneficial. Possibly a little adrenalin will help to stimulate the patient's blood pressure.

Pepsin in the Urine from the Standpoint of Diagnosis.—Strauss has examined the conditions in regard to the pepsin in the urine in twenty-three patients with carcinoma and twenty-two with non-cancerous aepsia. The result of his research demonstrates that too many factors are involved in the output of pepsin in the urine for it to have much specific diagnostic importance.

ELECTRO-THERAPEUTICS.

By JNO. J. MOREN, Louisville.

Electricity, that wonderful force which Marconi used in transmitting messages to the middle of the sea, which Edison used in his construction of a machine that would reproduce a song, etc., which Bell utilized in talking from Atlantic to the Pacific, that wonderful force which is the marvel of this day and no one is able to venture an opinion what will be accomplished by this force in the future.

Such is the position of electricity in the industrial field. Unfortunately it has no exalted position in medicine. However the doctor must give it credit for one favor, that is, it has furnished a better and more convenient light.

Soon after the discovery of electricity it was used as a remedy for various diseases. The church men opposed its use, but it's mystery and the claim of the charlatans launched it as a cure-all. From that time to the present, electricity as a therapeutic remedy has been rocking upon troubled waters. Some waves have been favorable, others have not. The over-enthusiast leads it to disfavor, the over-conservative does not restore confidence. The greatest drawback to electro-therapeutics has been, and is, the charlatan. It is astonishing what electricity is claimed to do. However, every branch of medicine, and the respective specialties have to suffer from the exaggerator and the money fiend. The laity believe that electricity can do anything. The electro-therapist has calls to remove hair and to restore hair; reduce flesh in obesity and develop the bust; remove wrinkles and improve complexion, and to cure all forms of diseases that the human body is liable to be afflicted with. It is utterly ridiculous to claim for electricity that which it cannot accomplish. It is deplorable to think how often it is used as a mere graft. It is indeed, hard to hold your tongue when patients tell you that they have had electricity and find out that the doctor has used a simple mechanical vibrator, etc. Personally, I have tried to use electricity for its real value and to avoid any enthusiastic claims, and results mentioned in this paper have actually occurred in my practice.

Electricity is regarded as a stimulating, sedative tonic. It is accused of that peculiar effect of causing a normal functional activity. If there be over or under glandular action it seems to favor normal function. A remedy which causes heart and respiration paralysis in large doses, ought to a greater or less extent, influence these functions in small doses. The various currents do influence circulation and respiration. It will cer-

tainly influence pain, and does influence nutrition. This effect is noted in delicate children who thrive under its administration.

The muscular system is distinctly affected, electricity being one of the few means of contracting a muscle even against the will. In addition you have a chemical effect as well as transposing substance from one pole to the other; cataphoresis, and electrolysis. Being a measure affecting so wide a range of symptoms, it is recommended in a great variety of diseases, but, as with other flexible remedies, it falls short in many instances.

Quinine is a good remedy, often used and often abused. If unsuccessful, do you condemn it? Electricity is a good physical measure, often used, often abused, so why condemn it?

ORGANIC NERVOUS DISEASES.

No reasonable man would expect any measure to restore wasted nerve cells. In destructive diseases of the nervous system, it is not a question of restoring functions, but to hold off loss of function in the progressive diseases and improve the remaining function which is impaired by the destruction of neighboring parts.

Take the common disease, locomotor ataxia. Any measure which will favor the nutrition and check the progress of the ataxia, is as valuable to this man as the knife is in cancer.

Can electricity affect this nutrition? I am satisfied that cases of tabes and chronic myelitis, have been favorably influenced. Not all, but a sufficient number to warrant its use until you are convinced that there is no effect.

In diseases like polio-myelitis, hemiplegia, etc., it is a question of improving the impaired function. The nerve supply to groups of muscles does not come from one segment of the cord; consequently, in many polio cases all muscles are not totally paralyzed, and by means of electricity and massage these muscles are developed to a better advantage.

Another side. Suppose you have a gummatous thickening of the meninges that refuses to respond to medicine. Many authors believe by the use of the galvanic current, which has a better penetrating power, you can stimulate this mass and thereby obtain results from drug treatment.

One often hears, "when you begin the treatment of electricity it has to be continued." This is absurd. The only explanation of such a statement, is the chronicity of the affection, and the patient still hopes for relief.

One advantage in all these cases is the temporary relief of the many troublesome symptoms. Those who experience such relief are grateful and satisfied that they do not have to resort to drugs which so often lead to bad results in chronic diseases.

PERIPHERAL PARALYSIS.

In ordinary cases of neuritis with paralysis, I am satisfied that results have been accomplished quicker by the use of electricity than without it. In fact I have had cases, as Bell's palsy, musculo-spiral, etc., under my observation that were slow and practically failed to respond to other measures, that improved promptly after electrical treatment.

If a motor nerve is destroyed by inflammation or otherwise, atrophy of the muscle will follow. The object is to maintain the nutrition of the muscle as far as possible and stimulate the growth of the nerve. Massage will help maintain nutrition, but by means of the galvanic current we can stimulate the muscle to contraction and thereby help the nutrition better than by massage, and in addition stimulate the nerve regeneration and hasten progress. No other remedy can replace the effect of the galvanic current in the treatment of these cases.

PAINFUL CONDITIONS.

It is a physiological fact that nerve irritability can be influenced by the electric current. The positive pole of the galvanic is sedative and diminishes nerve irritability and the pain carrying qualities of the nerve. The negative pole increases nerve irritability. The faradic current has practically no chemical effect and does not produce electrotonus as does the galvanic, however, being an interrupted and alternating current, the impulse or waves cause fatigue of muscle and nerve tissue, and for this reason, lessen pain. The effect might be compared to that of a vibrator. The static, especially the interrupted static, does have a marked influence over pain. Any of the currents can be used in the treatment of simple neuralgia or pain arising from various conditions with more or less influence, varying according to the cause and the pathological condition.

During the course of the year I meet many painful conditions, simple neuralgia, muscular rheumatism, herpes zoster, painful shoulder, sciatica, etc. In the treatment of sharp pain as in simple neuralgia, I prefer the positive pole of the galvanic. I have seen most satisfactory results from the galvanic in herpes zoster. In the treatment of painful shoulder, I have had the best results from the interrupted static. The static breeze and sparks are very useful in muscular rheumatism. In the treatment of rheumatism, gout, etc., I have never obtained sufficient results to use electricity in any of its forms. Many of the cases have been referred to me for treatment, but I rarely use it except, with the object in view to satisfy the patient that it is of no value.

In patients who are under treatment for

other conditions, who had the small acute Herbedin nodes, I have applied the static sparks with results in some cases, but in those that were confirmed rheumatics, and whose joints were permanently injured, no relief has followed. The muscular wasting from non-use following rheumatism, can be improved and give the patient more power.

GASTRO-INTESTINAL DISEASES.

In the *Boston Medical and Surgical Journal*, April 6th, 1911, one of the most prominent surgeons in the west, makes the following statement in reference to gastric ulcer: "Among the protean manifestations of neurasthenia, stomach complaint is the most common. This group of cases has given rise to many fads in medicine. Eminent gentlemen have asserted that no case of gastric ulcer should be operated upon until the patient had had his eye-strain corrected. Authorities stated that gastric ulcer was more common in women than in men, and that distress in ulcer followed at once upon eating. Osteopathy, Christian Science, walking barefoot through the grass, Lydia Pinkham's remedies, and Pierce's, as well as our own favorite prescriptions, and that time-honored fad, that loaded-dice and shell-game of the medical profession, "electricity," all achieved about the same results in the treatment of these conditions." If I have been rolling loaded dice or operating a shell-game, my apology is that I did not know it, at least the authorities have not closed my shop. I do not believe that such a statement should go without challenge, and coming from such a source it is bound to affect medical opinion.

Success in one line of medicine does not entitle one to make unjust criticism of other departments. The electro-therapist has equal right to accuse this surgeon of being a butcher.

No conscientious man would claim to influence gastric ulcer in any of its forms by electricity, but how about those atonic conditions with their long train of symptoms which may lead to ulcer? Is it not rational to use the electric current to restore that lack of tone? Many authorities believe that it does have such an effect by influencing both the voluntary and involuntary muscle fibres. There is no doubt in my mind, but that many gastro-intestinal troubles, particularly the atonic, are materially benefited by the electric current. I unhesitatingly advocate it as an adjunct to other appropriate medication directed to the particular ailment. The reaction or effect upon the circulation produced by the static has been of material help to me.

FUNCTIONAL DISEASES.

In functional diseases electricity is at its

best. In most instances the basis of the trouble is a disturbance of nutrition, and the effect is particularly noticeable. Take that great class, neurasthenia, with cold hands and feet, irritable and restless sleep, rapid and irregular circulation, vasomotor disturbances, in fact that large group of symptoms dependent upon nerve weakness and irritability. By the judicious application of electricity and appropriate tonic medication, you not only influence their misery temporary, but favor their nutrition permanently. So often have I seen improvements in sleep, relief of their parasthetic headache, better digestion, then better strength and stability.

Not all cases of hysteria should be treated by the lash. Remember that metabolic changes, as in anemia, changes of life, etc., often bring out an emotional disturbance, resembling profound hysteria, that responds to treatment directed to improvement of nutrition.

I like the static in these cases, but results can be derived from general galvanization and faradization. One point which I have noted is that patients assimilate iron with better results while taking the static current. Not all by any means, of these morbid necroses and psychoses respond. Heredity and environment must be considered before condemning the results of any remedy. However, in any nutrition disturbance, electricity can be used.

This large class of functional disturbances bring up the psychic effect of electro-therapeutics.

It is with regret that so many people look upon the effect of electricity as purely psychical. There is no doubt in the world that it can be used as an agent to influence the mind. Do we not give bread pills and simple remedies just to satisfy the patient? Do we not give remedies expecting little effect, hoping to keep the patient under observation until we are able to satisfy the patient that he is or is not curable. What few remedies can be used with less harmful results than electricity, and at the same time have a psychic effect? I deplore the fact that a number of physicians possess elaborate electrical outfits in their offices with the sole object of increasing office practice, without a conscientious intention of following the rules of electro-therapeutic practice.

The results obtained under these influences will be disappointing, and the batteries will be stored in the attic, and the doctor will condemn electricity. I have used electricity for the psychic and in many instances I depend upon the psychic effect absolutely. Again, I use it as an agent or means to have the patient report to the office that I might help influence his condition by explanation

and teaching; that he may become more self-confident, less introspective, in fact, know "where he is at." When used in hysterical conditions or morbid psychoses as a remedy, or as a means to influence the patient to the good, it is legitimate practice, but to be used as a means of fattening the pocket-book, is an injustice to the patient, and causes the profession to lose confidence in it.

A great variety of diseased conditions from sprained ankle to diabetes, have been referred to me by my doctor friends, with the hope that electricity might offer them some comfort. Frequently I have used it with results satisfactory to those concerned, but in most instances the treatment is discouraged. Should I follow the tactics of the charlatan, I could more than treble my practice, but money is not all. My policy has been, and I ask you to remember its effect is limited, but the results are sure within its restriction.

The wonderful claims made by the charlatan should not be used against the conservative doctor.

DISCUSSION.

W. F. Boggess: Dr. Moren has given us a most excellent paper. Electrotherapy has a positive place in medicine and it should be used for what it is capable of doing. The reason it has been so much condemned is that it has fallen largely into the hands of charlatans and quacks, and because, as Dr. Moren has said, it has been used for the purpose of producing revenue. Any man who depends upon medicine alone for the treatment of disease is not a competent doctor. The various extra-therapeutic measures, such as electrotherapy, hydrotherapy, etc., should be employed when indicated, but no man should use them unless he knows positively the indications for their use. Even admitting that they only do our patients good psychically, they are worth while. If we can cure our patients of imaginary troubles by the use of electricity, hydrotherapy, massage, suggestion, or what-not, it is just as much our duty to employ these measures as to give them remedies for actual disease.

The paper is a splendid one, and if I would have any criticism to offer it would be that Dr. Moren has been a little too conservative in the limitations he places upon this measure.

J. Rowan Morrison: The subject of electricity is a very interesting one. Electricity is a vital force; it is very essential to life. In one respect they are similar; we know something about life and we know something about electricity, but what either of them really is we cannot say. However, electricity is a vital force, and it does produce an effect upon the body. Therefore, if it be properly used, I believe that in many nutritional conditions it will do much good. That electrotherapy has been more or less discredited we all know; but I believe that if the charlatans

and quacks would take it up as actively as they have electricity, they would bring discredit upon even an agent like castor oil.

Not only should we know when to give electricity, but it is also essential to know how to give it. A certain amount of skill is necessary in giving electricity, just as in administering other measures; for instance, one man may give a patient digitalis and make him infinitely worse, while another man may administer it in such a way as to do the patient a great deal of good. The same is true of electricity. I have seen patients whose symptoms had been made worse by electricity go to men like Dr. Moren and be relieved by the same measure, showing, to my mind, that we must not only know when to use it, but how and in what doses it should be administered.

Andrew Sargent: I wish to thank Dr. Moren for his most excellent paper. I am very skeptical, personally, as to the beneficial or curative powers of electricity. We can only consider the claims for any measure in the light of results obtained, and the results from electricity in the hands of the general practitioner have been very disappointing.

The essayist did not mention the use of electricity in narcotic poisoning. I believe one of the most valuable purposes to which I ever put a galvanic battery was in a case of morphine poisoning. I remember one case in particular, which I wish to cite because the termination was rather funny. This was a brother practitioner who in an attempt to commit suicide, took an enormous quantity of opium, and, in addition a large quantity of belladonna, and when I saw him he was thoroughly narcotized, being perfectly unconscious and his extremities were cold. First I pumped out his stomach, and then placed him in a tub of hot water to keep him warm. Then I fixed up the battery, and when I got it working good I applied it to him, and when his consciousness began to return he imagined that he was in the lower regions. This impression was so strong that, upon looking up and seeing his wife, he cried, "Are you here, too?"

N. D. Abell, Princeton: I have had some little experience with the static machine, and it seems to me that the general practitioner's greatest trouble is due to the fact that he does not understand electricity; if we understood it more thoroughly I believe we would derive more benefit from it. I have used a static machine for a number of years, and I have gotten some good results from it.

Curran Pope: This paper deserves commendation. Dr. Moren left out one important point, which I am sure was simply due to a lapse of memory; that is, the value of electricity as a diagnostic agent in all peripheral lesions. It is astonishing how often we can not only diagnose the condition and its location, but very frequently we can prognosticate how long the

trouble will continue simply by the varying reactions of the current. It is essentially the nearest approach to a scientific electrical diagnostic agent in these lesions that we have at our command.

The main difficulty that I have found in connection with the application of electricity is that most men do not seem to appreciate the value, quantitatively or qualitatively, of the various currents. I think that, in most surgical conditions, the surgeon has a very rational idea of the value of the various procedures that he employs, but my experience has been that the **average practitioner** seems to have the idea that electricity is a very adaptable body that can be made to fit both a square and a circular hole at one and the same time. Each electrical current has its value, its place, and its use, and it **should be used only where it is of value and indicated.** The practitioner should be clear-minded and logical enough to understand, that when he uses a faradic current where a high-frequency current is indicated, **the fault does not lie in the agent employed but in his own cerebral machinery.** One certainly would not expect to check hemorrhage with a high-frequency vacuum tube; it will increase it. Yet we often see men possessing only one current attempting the impossible.

The next great difficulty is in connection with the clear differentiation of the polar responses. What pole shall I use, the positive or the negative? Gentlemen, one is night and the other is day. It is one of those things a clear comprehension of which will produce results; otherwise failures. If you have hemorrhage and you use the negative pole galvanic current—more hemorrhage. If you wish the stimulating, drying influence of the galvanic current, for instance, intra-uterine, would you employ the negative pole? Not at all—the positive pole, using some pure metallic body like copper or zinc amalgamated with mercury. When one fails to accomplish results with the proper current in cases where it is indicated, he should ask himself, “Where have I made my mistake?” and not condemn the agent.

Now we hear a good deal about electricity and charlatanism. Let us see if we cannot arrive at some understanding. **Nothing of itself constitutes charlatanism; it is the method of its use.** Therefore, any agent, any idea, may be the subject of charlatanism; it bears no other relation to it than that. It is a very simple, clear psychological proposition; exceedingly so.

I think I can demonstrate to any reasonable and rational practitioner (and I have to a great many in the city of Louisville), that I can dilate the cervix without local or general anesthesia, and absolutely without pain. I have done it for a great many people, and it can be easily done. But one must know.

Now, I would like, with the kind permission of my good friend who spoke first, Dr. Boggess,

to ask him, and to ask you all, to watch out for **“this imaginary business.”** According to the latest work that is being done in psychology, there is nothing that is without its rational, well-defined, reasonable cause. Just as the laws of physics of the universe are fixed—just as the apple falls in obedience to the law of gravitation, so your mind and my mind act under just as fixed laws, and your response and my response is determined exactly by what exists, and not by any “imaginary” condition. So much is this so that Jung and the Zurich School have determined that even the wildest ravings of a lunatic are **determined**, are governed by actual fixed psychological laws. Therefore, I say to you, watch out about calling **anything** imaginary. It may look that way on the surface, but when you consider that the **conscious life of an individual is the smaller part of that individual's psychological make-up, you will realize that you must be exceedingly careful as to what you call “imagination.”** Freud has lately demonstrated, in a masterly work, that even the play of children is absolutely based upon determining factors that enter into the individual's life history, and that even in choosing numbers, as has been lately shown by Jones, psychological analysis will reveal that the number chosen by the child is predetermined by certain factors in that child's life.

Hysterics are not so everlastingly suggestible. Freud and a great many other workers have abandoned hypnotism, because they found it so difficult to succeed in a large percentage of cases. Now, gentlemen, these are facts which any of you can go to the literature and verify for yourself. The hysteric is not such a simple and suggestive individual; on the contrary, as a rule, the hysteric is really one rather unsuggestible. If she were so easy of suggestion cases of hysteria would not hold on so long and be the **bête noir** of the profession. There is piling up page upon page and volume upon volume of literature to bear this out. The ideas we have heretofore entertained about people and things will have to undergo reconstruction, and this is particularly true of the idea that electric currents act through suggestion. Many individuals who have been terrorized, at first, have received benefit from electrical treatment in spite of their terror. That certainly is not suggestion. On the contrary, we find that the doctor can frequently persuade a patient to accept the treatment in which he has no faith; he accepts it under protest, and yet receives much benefit.

A great many symptoms of hysteria are the result of previously existing trouble, and it is in these cases that the greatest benefit is to be obtained from hydro, electro and mechanotherapeutic and similar measures. The patient is benefited simply because there was actual trouble before the psychic state of the individual pounced upon and used it. We must try to keep absolutely clear in our minds the condition we have

to meet—the patient herself or himself, and keep absolutely clear and distinct the physiological action—what can be accomplished by the current on one man but not on another, and by bringing those two together in a rational, clear, sensible way, we can get results.

A lady walked into my office this morning and said: "Doctor, can you cure my hearing by electricity?" I replied: "No, Madam, and I won't try it; I do not think it can be done." I gave her a letter to an eye, ear, nose and throat man, and told her she had better go to see some good specialist along this line, and that my advice would be not to have the electric current applied. There are some things that it is wisest not to start. A man of experience knows those things and cuts them out at the first chance. I think it would have been a mistake to have started to do anything in this case. I do not know what is the matter with her, but I do know that some of the greatest failures of some of the best men have been in connection with deafness. That is a problem for the man in that special line of work, and not for the electrotherapeutists in any sense of the word. I take it that electrotherapy occupies no other position than does diet, fresh air, hygiene, drugs, mechanical vibration, exercise, resistive movements, psycho-analysis, psychotherapy, etc.; it is one arm of an octopic therapeutic process, and the man who looks upon it in any other light certainly does not understand electrotherapy. There are certain cases that are benefitted by electrotherapy; there are certain cases that are benefitted by this, that and the other, and I will venture to say that there are exceedingly few doctors, who make a special study of this line of work, who venture to depend upon it alone. We must never forget the diet, exercise, drugs, etc.; never be a one-sided fellow. A man must be like the diamond, many sided, reflecting rays of light from all his surfaces; being open, like the diamond, to receive the light, and spreading it to his patients as the diamond does to the world after it is cut and set. Whenever you take that position, whenever you consider that you have in electrotherapy an agent, just as you have a *materia medica*, let us say, and that you intend to use your drugs and your electricity and what-so-ever-you-choose in the treatment of your patients—whenever you come to look upon it in that light, and to regard it as it should be regarded, as your handmaiden that you are trying to utilize to cure your patients, you will get away from a great many foolish ideas. I am sorry to say that many men are like a distinguished gentleman who read a paper before this society, and stated that he had used Bier's hyperemia and was exceedingly astonished to find how mistaken he had been in his ideas regarding that treatment after he had begun to use it right. Some of you who are doubtful and skeptical should stop and say, "I don't know;" ergo, "My opinion is not worth anything." That is the only conclusion

one can come to. I don't know Sanskrit; therefore, of what value would my opinion be in connection with the translation of a Sanskrit stone? What do I know about the written language of Memnon? Nothing. I let it alone. My advice to any man is that unless he knows and understands electrotherapy, let it alone. It is not altogether the charlatan who has blackened the fame of some therapeutic measures; it is also the physician who **don't know**. Gentlemen, the truth may be disagreeable and unpleasant, but sometimes when we are told the truth it acts as an incentive to the acquirement of more knowledge and does a great deal of good. If those who do not know and want to know will turn their faces to the East and try to gather a little light, I think they will find, just as I have told you, that electrotherapy has its value, its use and its place.

John J. Moren, (Closing): Gentlemen, I teach the subject of electrotherapy to the students at the college, and I have a most ungodly hour—from five to six p. m., when everybody is hungry and wants to go home, but in spite of this I have an average attendance of from 80 to 90, and I think that is a very good attendance for such an hour and such a dull subject. These boys evidently feel that they should know something about electrotherapeutics. I do not know whether it is because they really wish to learn every branch of medicine, or whether they simply desire to get by the State Board, but anyway they come. One of the first things that I try to impress upon these boys is that, whenever they hear a man say that there is nothing in electricity, to ask him whether he has ever used it and, if so, how long. Nine times out of ten you will find that these men have either had no experience with electricity at all, or that they have a small battery which they have used two or three times, and being too lazy to keep it in order, have shoved it to one side and then gone about condemning electricity. I am satisfied that they do not know whereof they speak. However, one of the best men in Louisville claims that electrotherapy has no value, and to him I say that my office is open, and if he will bring a patient there with a condition that is apt to be influenced by the electric current, I will demonstrate to him that it will do good.

One great fault in connection with the use of electricity is that some men go ahead and use it without stopping to consider whether or not electricity can have any influence upon the particular condition they are treating.

Speaking of hysteria, I will say that recently a physician sent to me a young girl whom he had been treating for aphonia for the past six weeks, without any benefit. He had used all kinds of remedies, including iron, phosphorous, and sedatives of all sorts, scolded her, etc., but without avail. When she came to my office I noticed that she had a complexion of a greenish cast, a sort of chlorotic complexion. I started this girl on iron

in conjunction with static electricity, and I never saw such improvement in a patient's complexion as occurred in this case. In three week's time she was using her voice, her skin was clear, her eyes bright, had a good appetite, did not feel fatigued and slept well. I attribute this improvement to the use of iron which the electric treatment helped her to assimilate. I am getting so now that every time I see one of these anemic individuals, I give them iron with static electricity, feeling assured that the patient will be benefited by it.

Again, in old persons, with arterial changes, causing cramps in the calf of the leg, with an irregular, arrhythmic pulse, the results from the use of static electricity are simply astonishing. The pulse becomes regular, the cramps disappear, and the individual, instead of waking up at two, three or four o'clock in the morning, is able to sleep all night. Of course, the relief is only temporary, but it gives these patients a degree of comfort that cannot be obtained by the use of any other remedy.

I wish to utter a word of caution in connection with one feature mentioned by Dr. Pope. He spoke about stopping hemorrhage with the positive pole. While attending a surgical clinic in the East (I do not remember just where), I distinctly recall that the surgeon after removing an uterus, held it up and said: "Gentlemen, here is an uterus that has suffered at the hands of the electrotherapist." He cut the uterus open and showed that it had practically no mucous lining. Now, what had the electrotherapist done? He had used the positive pole, which hardened the tissues, contracted it down upon the electrode, and when he pulled it out he brought with it practically all of the mucous membrane. Dr. Pope's position is right; it will do what he said, but before removing the positive pole I would advise that the negative pole be switched on so as to loosen up the mucous membrane.

Don't tinker with electricity. Be sure of what you intend to do and how you are going to do it before you proceed, and I am satisfied that you will be pleased with the results.

Curran Pope: I rise to a point of personal privilege. In connection with Dr. Moren's last remarks, I will say that we can slip the positive pole out of the uterus, without switching on the negative pole, as easily as we can peel an onion, provided we know that the pole should be amalgamated with mercury before it is introduced, in which event it will not adhere to the mucous membrane. I wish to emphasize Dr. Moren's last remark—we must know what we are doing.

The Cammidge Reaction.—Weber describes the mechanism of the Cammidge reaction and states that it is a not to be underestimated sign of abnormal conditions in regard to pancreatic secretion.

SOME REMARKS ON ALBUMINURIA.

By J. ROWAN MORRISON, Louisville.

"One swallow does not make the Spring," and on the contrary I have stood on a day when the Spring was in its fullness and scanned the far heavens without seeing a swallow. The mere presence of albuminuria does not mean that a nephritis exists, nor does the absence of albumin from the urine mean that the kidney may not be seriously diseased.

Much work has been done upon the subject of nephritis recently, still the last word on this condition has not been spoken yet, and I will not try to speak it here this evening; far be that from me, I only want to bring together here some observations gathered from some of the more modern text books, by authors of repute and touch upon some recent medical papers on this subject, and then report a few cases along these lines.

Domenico Cotugno in 1770 discovered an albuminous substance coagulable by heat in the urine of persons afflicted with dropsy and diabetes. This discovery, however, only led to the differentiation between dropsy with albuminuria and that without.

Bright in 1827 brought forward his masterful papers at Guys Hospital, London, in which he proved that many forms of dropsy originate in diseases of the kidney manifesting themselves by the presence of albumin in the urine. Bright, and later Rayer, covered their subject in such a masterly way that a great deal of interest sprang up in the subject of kidney disease and albuminuria, so that their work is still alive and probably all of us, until lately have found it difficult to disassociate albuminuria and nephritis. (Herrick in Nothnagle's System of Medicine remarks on the masterful presentation of this subject by Bright and Rayer).

Therefore, it was not until the later advancement of physiology, chemistry and biochemistry, pathology and bacteriology that we have learned to go beyond these conclusions and approach nearer to the truth, nevertheless considering the amount of work necessary in so large a subject and considering that in many respects many of the above mentioned sciences are just now coming into their own, it is no wonder that much remains to be known definitely about kidney diseases.

ALBUMINURIA NOT NEPHRITIC.

I want to state now that I refer in my remarks to so-called true or renal albuminuria as distinguished from false or infrarenal albuminuria due to pus, blood, semen, etc.

Physiological albuminuria. Morner has proven that albumin (serum albumin) is a constituent of normal urine in 22 to 78 mgm per liter (.0022 to .0078 per cent).

Nucleo albumin, which was also called mucin, Morner has proved to be a combination of serum albumin with substances that precipitate albumin, as chondriotin sulphonic and thus proving that the albumin precipitated by cold acetic acid is really a serum albumin. However mucin may exist in urine, but does not contain phosphorus, chemically. This disproves Von Noorden's statement that physiological albumin is nucleo, rather than serum albumin.

In the minute proportions mentioned above, albumin cannot be detected by the ordinary tests, but only by special delicate methods, however, there are many cases, especially, in the young and adolescent where albumin, often in very considerable amount, is detected by the ordinary means, and is often accompanied by hyalin casts, although these cases present none of the ordinary symptoms of nephritis. The exact cause for these so-called functional albuminurias has not been definitely settled, although many reasons are offered as to why the renal filter allows albumin in such quantities to pass.

While there is a similarity in almost all the cases of these functional, intermittent, cyclic or orthostatic albuminurias, each case or group of cases seem to present a preponderance of causes in certain directions. In all there is absence of albumin at times, they are intermittent. They are usually cyclic, however this is not altogether untrue of nephritic albuminuria. They almost always disappear when the subject is in the recumbent posture, and appear after standing or assuming the erect posture. They are almost always found in what is known in the neurotic type, but by no means always. They are not associated with serious changes in heart or circulatory system. Only the ordinary excitability of the Cor Jeevenum of Krehl usually being found, and in almost all cases the albumin entirely ceases to appear as the patient grows older, and leaves them none the worse.

The condition is most frequent between five or seven to twenty-five years, and centers especially about puberty. It is much more frequently observed in males, however it is probably more frequent in girls than is supposed, and only overlooked because they are not studied in this direction. Rapid and inordinate growth has a large determining influence according to Goodhart. He took the average weight of 124 cases. Forty-eight were under average, 76 over, and many very much so. Taking height, 106 cases, 23 only were under average height and several of these had grown rapidly lately. Eighty-three over the average height, some as much as three to eight inches.

Posture plays an important role, as most

frequently the urine passed before arising or just after arising has no albumin whereas that passed in midmorning after the subject has been standing may be full of albumin. However, this is not invariably the case, as Senator notes cases where there was more albumin in recumbent posture than in erect. In regards the effect of posture in the production of albumin, the observations of Jehle as to the effect of lordosis either as a disease process or produced by kneeling in a certain way are interesting.

Dr. F. Parks Weber, noted lordotic cases in which albumin could be made to appear while the patient was lying in bed by placing a bolster under the small of the back.

Senator remarks that the upright position tends to retard the flow of blood in the ascending vena cava and its tributaries thus producing somewhat of a stasis in the kidney. Henderson and Krehl have shown that slowing of the blood current in the kidney tends to produce an outflow of albumin.

Overexertion is often the cause of albumin in the urine, and especially that form of exercise where the subject is sitting and using the lower extremities, especially as rowing, bicycling, etc., although it sometimes appears in prize fighters, and long distance walkers.

Dr. William Collier, of Oxford, speaking of athletic albuminuria said he thought he would really find out what happened in rowing, so he made arrangements to get the urine of many of the college crews. One hundred and fifty-six cases were examined who were in training for the Lent races. He used the cold nitric acid test. Out of 156 men, 130 had albumin in the urine, some in large quantities, some only a small amount. In 1907 he took the urines of five crews that had actually raced. Every one of forty men examined was passing albumin and many passed casts, some of which he believed were granular casts. He believes the albumin due to a passive congestion of the kidneys. The albumin usually disappeared in five to six hours after the race. The urine of runners frequently contains albumin. In 38 reports by Dr. Collier, 37 contained albumin.

That the albumin is not the result of irritation due to the end products of muscular exercise seems to be shown by Dr. Collier's reports in examining the urine from eleven men who had just completed a 24-hour walk, none of these having gone less than 100 miles, one a man 66 years old. In only three instances was there albumin, and then in only small quantities.

DIGESTIVE ALBUMINURIA.

The ingestion of large quantities of heterogeneous albumin as egg albumin or milk (cows) albumin in too large quantities will

produce albuminuria. Goodhart says that he does not believe posture alone will produce albumin, but posture plus breakfast will, especially as in the class of cases this trouble is found, the digestion is liable to be faulty and the proteids not completely prepared when they reach the kidney filter.

Cold baths and falling into and wading in cold water are not infrequent causes.

EMOTIONAL CAUSES.

That the deeper emotions, as grief, fear, etc., can produce albuminuria is noted by Senator, Krehl and many others.

Dr. H. G. Armstrong, medical officer at Wellington College, remarked: He did not think it was recognized how frequently extreme emotion, especially fear would cause albumin to appear in the urine. If the urine of extreme micturition which attacked a boy when about to receive a promised flogging, could be examined he felt sure albumin would be found in it. He knew of many cases where it was.

BLOOD PRESSURE.

Ebel, and later Hooker and Erlanger state this form of albuminuria is associated with marked change in blood pressure. Oliver denies this.

Dr. Armstrong took the pressure of boys on the day before they went on long distance runs, and then an hour and a half after the run. If there was lowering of pressure there was albumin. Albumin continued as long as there was lowered pressure. In some of the marked orthostatic types he (Armstrong) found that instead of the pressure rising on assuming the upright position it dropped 10 to 15 mm.

After all the real cause does not seem to lie in any one of these conditions, but frequently in a combination of many or all of them. I am convinced that there is much truth in what Dr. Goodhart said in summing up his paper on "The After Histories of Cases of Albuminuria Occurring in Adolescence," read before the Royal Medical Society. "My own explanation, as I said in my opening is; not that they are albuminurics; not that they are cases of low blood-pressure only, but that they are machines with their petrol exhausted, their nervous energy all gone for a time; and these unnatural signs are an indication of the upset of function caused thereby."

"Adolescent albuminuria is largely an affair of growth and development. Not entirely so, for I am sure, with Dr. Armstrong, that an emotional temperament is often behind it. These things, I take it, act upon and lessen vasomotor control and link up the condition with such phenomena as flushing and blushing, a poor circulation as it is called, and blue hands and blue brains, and with—not renal

disease—but that large subject of angio-neuroses and intermittent claudication suggested in my opening."

As regards the frequency of functional albuminuria Dr. Armstrong believed that if a urinary census were taken of a large public school like Wellington College, where there are 500 boys, 15 per cent would be passing albumin. Dr. Clement Dukes from Rugby School reports that in eight years he had made a physical examination of 1000 boys entering the school, and of boys between 13 1-2 and 14 1-2 years 157 were passing albumin.

WHAT IS THE RESULT OF SUCH CASES.

Krehl says, "So far as I know, it has not been definitely proved that a single case of this form of albuminuria has ever become transformed into a true nephritis. I have observed a number of such cases myself over long periods of years, and have yet to see such a transformation, and I am therefore personally inclined to regard these as relatively harmless. Yet more time must elapse before the prognosis of this form of albuminuria can be definitely settled."

Goodhart says, "Albuminuria of the adolescent has no sinister effect upon health, or upon the duration of life, and that with due circumspection such cases ought not to be excluded from the advantages of life insurance, or from clerkships in banks and other public and private offices.

Senator does not hold such a hopeful view and does not allow such latitude for physiological albuminuria.

I believe that the insurance companies in this country will admit this class of cases now if they can show three consecutive negative specimens after one positive.

We must not forget that true nephritis often exists in the young and adolescent. Here the symptoms are more pronounced and most frequently there is evidence in the cardiovascular system.

Tuberculosis of the kidney may manifest itself by little else than an albuminuria, caused by a localized tubercular nephritis. Here a diagnosis can be made by examination of urine for tubercular bacilli, and its injection into a guinea pig.

TREATMENT.

Treatment consists largely in not treating them, but showing the way to proper development. They should certainly not be treated like nephritics.

NEPHRITIC CASES WITHOUT ALBUMIN.

We now pass to the opposite side. All competent observers know how often a severe chronic nephritis may exist without a trace of albumin or casts. It is true that most of these cases will show a trace of albumin and a few or many cases if careful prolonged examina-

tion is made for a long time, however this is often not feasible or not done, and a bad nephritis is overlooked. So one here, to do his full duty must make a most careful general physical examination, and when possible supplement this by some of the tests for renal insufficiency. Symptoms in the different systems taken alone may not mean much but thoughtfully and carefully taken together after allowing us to make a diagnosis of nephritis where there is no albumin or casts present.

The cardio vascular system gives us our most valuable symptom. An enlargement of the heart to left with an accentuated second sound, and gallop rhythm does not mean nephritis, but taken in conjunction with its usual accompanying high blood pressure and its concomitant symptoms, it must be explained on some other basis, before we can exclude nephritis. Examination of the retina with an ophthalmoscope often gives signs of vascular changes early in such cases, although many severe cases do not show signs there. Vertigo must not be overlooked nor numbness in the extremities and cramp and pains in the calves of the leg. The nephritic is always anaemic, and in many of these chronic cases the blood picture takes somewhat the chlorotic picture. Oedema, even though very slight is a valuable symptom. Itching, nausea and vomiting, and chronic cough must be investigated and explained.

Increased urine and increased frequency of urination should be studied in relation to other symptoms.

None of the above detailed phenomena alone mean nephritis, but taken together or in groups or when not to be explained, must at least cause us to place the kidney under suspicion. Many tests, chemical and physical have been devised for determining renal sufficiency or insufficiency. Suffice it to say they have not been very successful so far.

The determination of the urea in a single specimen is of no value at all.

Cryoscopy or determination of the freezing point of the urine is of very little practical value as the freezing point of urine varies so much normally. It is of value when the urine from the separate kidney is compared or when taken together with the freezing point of the blood. Here the trouble is very great.

RENAL PERMEABILITY.

It has been recognized for quite a while that certain drugs and some of the normal constituents of the urine are not so readily eliminated as in health.

Methylene blue has been used to test this permeability for some time. The color begins to appear in the urine in half an hour, and the elimination lasts for from 16 to 60 hours. In disease it may not appear for several hours,

and its elimination is prolonged considerably over the normal, or in some instances this time may be shortened. The great length of time in which the total amount of urine must be collected and the amount of methylene blue estimated make this test unsatisfactory and besides many clinical observers have shown it to be unreliable. Widál reported a case of syphilitic nephritis in which the elimination was normal, although the patient was suffering from a severe uremia. In chronic parenchymatous nephritis many observers have shown that the permeability is normal or increased.

ELIMINATION OF CHLORIDES.

If we know the amount of chloride of sodium taken in the diet of a patient for some days and compare this with the chloride eliminated we arrive at the degree of renal permeability.

PHENOLSULPHONEPHTHALEIN TEST.

Geraghty and Rountree of Johns Hopkins University have introduced this as a test for renal sufficiency. Phenolsulphonephthalein is a bright red crystalline powder, first prepared by Rensen, and has been proven non toxic in quantities in excess of amount used in test; it appears in the urine normally in a very few minutes after its injection, imparting in the presence of alkalies a bright red color. The technique in brief is as follows: Twenty minutes before the drug is to be applied the patient is given 300 or 400 cc. of water to insure passage of urine. Just before the injection is given a sterilized catheter is inserted in the bladder, then an injection of 1 cc. of fluid containing 6 mgm. are introduced subcutaneously. The catheter is placed in a test tube containing a drop of 55 per cent solution of caustic soda, and at first appearance of a pinkish color noted would indicate the time of first appearance of the drug in the urine. This ordinarily occurs in from five to eleven minutes. In ordinary cases the catheter is withdrawn, but if there be prostatic enlargement, let the catheter remain. The urine passed the first hour, and again at the end of the second hour, if taken by the catheter, the urine at these times are noted. In normal conditions about 50 per cent of the drug is passed in the first hour, and up to 75 to 80 percent in the next hour. This can be determined by a colorimeter devised by Hellige and Rountree. They have found results to be very uniform. In cases of slight parenchymatous nephritis there is only a slight diminution in the amount secreted in first hour. In cases of chronic interstitial nephritis, and in cases of uremia the time of appearance is prolonged, and the amount passed in the first hour is greatly reduced. It appears that this test will be of great service as the whole examination can be made in a very short time.

They have used this test a number of times in determining the relative efficiency of the different kidneys and claim that it works very well indeed. It appears that in this test that we have much to look forward to in the determination of renal efficiency and inefficiency.

TREATMENT.

Sparing the work of the kidneys by observing the food and drink as shown in the work of Von Noorden. Vicarious elimination through bowels and skin.

Case No. I. Young man 19 years old. Had been refused insurance on account of albuminuria. Examination of midmorning urine showed considerable sign of albumin. First morning urine showed no albumin. Never found any casts. He was nervous and very introspective. Under suggestive treatment, and more normal mode of living albumin disappeared, and only appeared occasionally. He showed no cardiac or vascular changes. He has quite recovered and has been insured.

Case No. II. A friend of mine, a physician, at fifteen albumin was noted in his urine, was cyclic and intermittent. At 22-23 years he still had albumin and hyalin casts occasionally. General health good, no cardiac or vascular symptoms. He is now 36 and tells me he has been free from albumin for several years.

Case No. III. This is a most interesting case to me. In January, 1904, he was taken ill with a pharyngitis but his temperature continued several days and he developed some abdominal symptoms I began to suspect that he might have typhoid. I examined his urine for Diazo reaction. This was positive, but free from albumin. For several examinations there was no albumin. At the end of ten days the Widal reaction was negative, but about this time albumin began to appear in the urine in considerable quantities. The urine also showed hyalin casts. The albumin continued in the urine for about a month, and the young man seemed to return to about his normal state of health. After this I examined his urine occasionally. Sometimes I found albumin, sometimes not. Midmorning specimens more frequently contained albumin than not. He went away to college. I only saw him at Christmas, and during his summer vacation. Usually at the Christmas holidays, when he first returned, being tired, the urine contained albumin in the midmorning specimen, but by the time he returned to college there would be only a small amount, and sometimes none. He went along this way, living a normal life, and not complaining of anything unusual, except that he had a sluggish bowel, considerable intestinal putrefaction with the urine showing large amounts of indican. He seemed to develop normally, and did not show

any cardio-vascular symptoms at all. In the summer of 1911 he came to me complaining of a considerable amount of weakness and dizziness. I found that his midmorning specimen was full of albumin and indican. The specimen taken before rising showed only a trace of albumin. Being considerably run down and having a great amount of intestinal putrefaction I decided to send him to West Baden Springs, and had him put on a low proteid diet, thinking that the free elimination there would cut down the indican, and that this might have a beneficial effect upon the albumin. He was there for ten days on the low proteid diet, and eliminative treatment. The indican almost entirely disappeared from the urine, and the albumin was somewhat reduced, even in the midmorning specimen. He returned after ten days feeling somewhat better with still a trace of albumin. He then began his usual work, which required riding a considerable distance on a motor cycle. Immediately the urine began showing large amounts of albumin. After discontinuing the use of the motor cycle the albumin was greatly diminished, being practically none in the specimen before rising. I decided to send him to California that he might lead a more out of door life and have the benefit of the bracing climate. He was there examined by one of the foremost internists of the Pacific Coast who agreed that he had no manifestation of nephritis, and that the albumin was only accidental. The patient writes me that he feels quite well, and rarely passes any albumin now.

Case No. IV. Colored man age 54, teamster. First saw this man May, 1911. He was suffering from severe attack of nausea and vomiting. First vomited food, after that a little watery fluid. Gave history of having these attacks for ten months to a year. There was no evidence of tumor in the epigastrium. Liver seemed to be normal, abdomen not distended. Apex beat in the nipple line sixth interspace, marked accentuated second aortic sound. Urine increased in amount, specific gravity 1010, no albumin, one or two hyalin casts in quite a number of specimens examined. Blood pressure 170 mm. From the history of vomiting I first suspicioned this man might have cancer of the stomach with obstruction, but as he immediately stopped vomiting on eliminative treatment I gave up this idea and placed him on a course of elimination for several months. He had no return of the trouble until September, 1911. During this time I made a number of examinations of the urine and found once or twice a very faint trace of albumin, and a few hyalin casts. He was still passing large quantities of low specific gravity. After extremely arduous physical exercise under stress he was again taken with

severe vomiting spells, which continued for several weeks. Several of my friends advised that I have his abdomen opened as they suspected obstruction of pylorus, however, under thorough eliminative treatment, vomiting ceased and he began taking nourishment without trouble. I now gave him at night a test meal consisting of a large quantity of meat and a handful of raisins. In the morning I washed out the stomach and found no evidence whatever of obstruction. He has continued to improve under eliminative treatment, and I feel sure this is a case of chronic nephritis with nephritic vomiting.

(Since this paper was read I have applied the phenolsulphonphthalein test on this man. The first trace of the chemical began to appear in twenty minutes; 20 per cent was obtained in the first hour and 14 per cent in the second hour making a total of 34 per cent, which is very far below normal.—AUTHOR.)

DISCUSSION.

J. B. Marvin: Bright's disease has certainly been promoted to Captain and now ranks next to tuberculosis and pneumonia as one of the Captains of the bands of Death.

In a consideration of this subject we are confronted with three or four propositions. First, the existence, in the normal urine, of small quantities of albumin. This, I think, can be disregarded. Next, those cases grouped under the head of albuminuria of adolescence, or so-called physiologic albuminuria. That means albuminuria without other evidence of renal changes. If there is no high tension, nor granular nor epithelial casts in connection with this, it may be of little pathological significance.

In my opinion, one crying necessity along this line is the standardization of tests for albumin. As long as we have various tests, some of them far too delicate for clinical purposes, we are going to hold discordant views about this kind of albuminuria. For all practical clinical purposes, the physician needs only two tests, and he is liable to fall into serious error if he goes beyond them unless he is qualified as a chemist, and even the best of chemists will tell you that there is great liability of error in the employment of the more refined tests. The tests I speak of are, first, heating the urine and adding a few drops of acetic acid; and, second, the cold nitric acid test. If we find albumin with these tests, we can label it an albuminuria, but with the other tests we are liable to err.

We cannot go to our text-books for the latest views in regard to albuminuria, because, so far as I know, they do not contain the latest researches upon this subject. We must go to our physiological chemistry books, and to those upon higher chemistry—physical chemistry as I discussed this subject in my paper last week. I will not go into this further than to offer one other suggestion. We have three things to bear in

mind in connection with the production of urine. First, the blood, consisting of a liquid part in which are floating various cells. The cells are colloid structures, jelly-like in character. Next, the urinary membrane, or separating wall between the blood and the urine. This is a jelly-like structure composed of various colloids in a solid or gel condition. Next, the urine, an aqueous solution of various colloids.

The statement has been made, time and again, as to why we have albuminuria (and it explains some things that Dr. Morrison referred to in his paper) that the albumin does not come from the blood direct, but from changes which occur in the separating wall or medium between the blood on the one side and the urine on the other. The acid products in the blood, acting upon this cell state, liquifies it, and makes it come out in the urine as soluble albumin. Possibly by physical exercise, plus diminished oxidation, an excess of acid is accumulated in the blood which liquifies the jelly and makes it soluble, and it appears in the urine as albumin. If this process is kept up for a sufficient length of time, pathological conditions will develop.

In conclusion, I wish to show the apparatus Dr. Morrison has referred to, namely, Rountree and Geraghty's modification of Hellig's colorimeter, with ampules of phenol-sulphon-phthalein, for making easy and accurate estimation of the renal function. One objection to it is that it costs too much money, the price being twenty dollars, and, in addition one dollar for ten of these little ampules, containing one cubic centimeter each. It seems to me that it could be sold to the profession for considerably less money than that.

R. Hayes Davis: During the past year I have been very much impressed by the frequency of the occurrence of physiological albuminuria. Five distinct cases have come under my observation during that time in connection with insurance examination work, and all five of these cases showed large amounts of albumin in the urine with the nitric acid test, the rings in some of them reaching a diameter of a quarter of an inch. I watched these cases from time to time, and all five have completely cleared up. They were all in young individuals, their ages ranging between 16 and 25 years. All of these were cases that had been postponed for periods of from two to three years because of albuminuria. All of them were entirely free from albuminuria at the time of my last examinations.

During the past week I have seen two young men who were postponed, less than a year ago, for a period of six months because of albuminuria. When I examined their urine a few days ago they were entirely free of albumin.

Most insurance companies recognize physiological albuminuria to the extent that they will accept any case if three negative specimens can be procured after one positive one. They also re-

quire a statement from the patient to the effect that he has had no special treatment for the condition, although, personally, I do not believe any treatment would affect it one way or the other.

F. C. Askenstedt: I have greatly enjoyed hearing this paper.

We cannot too greatly emphasize the points of differentiation between cases of so-called functional albuminuria and interstitial nephritis, and we should use every means at our command to do so. I do not think any of us can afford to do without the sphygmomanometer. High tension will nearly always be found in the presence of a nephritis, especially interstitial nephritis, while in the other cases it is normal or subnormal.

Dr. Morrison mentioned that an increase in the quantity of urine passed is usually found in interstitial nephritis, but one point that he did not mention is that this increase is most marked in the night urine. Of course, this is not true in all cases, and, furthermore, not every case where the night urine exceeds the day urine is a case of interstitial nephritis, but in all suspicious cases the day and night urine should be collected separately and sent to the pathologist, and where an interstitial nephritis is present it will almost always be found that the night urine exceeds the day urine.

I am very glad to hear a report on the phenolphthalein test. Some months ago I read an article in the *Journal of the American Medical Association* which stated that a very minute dilution 1-6 mgm., should be used, and that the solution would not keep very well. I understand that it can now be obtained in ampoules, which makes it very much more practical.

J. Rowan Morrison, (Closing): I wish to thank the gentlemen very kindly for their remarks.

As I stated in the beginning of this paper, I did not intend to bring forth anything new; that a large part of my remarks would be along the line of work which has been taken up in modern text-books and the ideas of prominent men upon this subject. My idea was to make us think about this subject a little bit and bring it up for discussion here.

In regard to toxins, this is a rather interesting question. Take, for instance, a case where we have toxic material thrown out from a sluggish bowel, and we find a large amount of indican, and other products of that kind, but many times we will find no albumin at all, while at other times it will be present. That would be rather against the toxic theory, although I am perfectly free to admit that we have not been able to determine exactly how albuminuria occurs.

THE TREATMENT OF ALCOHOLISM.

By B. J. O'CONNOR, Louisville.

It is obviously unnecessary to endeavor to attempt to set forth to physicians the importance of the many dire and disastrous consequences which result to the individual, the family and to society at large from the abuse of alcohol. The many problems both medical and social connected with alcohol have engaged the attention of the most brilliant men both within and without the medical profession.

By alcoholism, we understand a series of morbid phenomena that are directly due to the toxic effects which result from the excessive ingestion of alcohol. There are many late or indirect abnormal effects due to excessive and prolonged use of alcohol, which, although of greatest significance, are not included under this head. The subject for practical purposes will be considered from three standpoints: 1. Acute alcoholism or drunkenness; 2. Acute alcoholic delirium, or delirium tremens; 3. Chronic alcoholism, habitual drunkenness, or inebriety.

ACUTE ALCOHOLIC INTOXICATION.

The acute manifestations resulting from the ingestion of excessive amounts of alcohol depend, upon the quantity imbibed, the amount absorbed and the length of time to which the system has been exposed to overdosage. The first stage is that of stimulation or excitement; the second, a stage of incoordination with mental incoherence; third, complete unconsciousness or paralysis. When an overwhelming dose is taken within a short time, these stages follow one another with extreme rapidity, and when the quantity exceeds certain limits, a fourth stage, death, may be added. These effects are more accentuated in some individuals, particularly the young, the weak, those of a poor physical development and those unaccustomed to alcohol. From a physiological standpoint the elimination of alcohol by the breath, even though no distinct nervous symptoms are present should be regarded as a mild intoxication since the amount ingested is more than can be oxidized in the the system.

ETIOLOGY.

In this country the custom of treating is largely responsible for most of the drunkenness. "Goodfellowship" and "sociability" lead the weak-minded and ignorant to overload their system with an intoxicating beverage. In other instances worry, anxiety, disappointment, physical or mental strain, nervousness, insomnia and other conditions induce the individual to seek in alcoholic beverages a stimulant or a sedative. Occasionally intoxicating quantities of alcoholic drinks are taken in ignorance of the amount of alcohol or the

effect thereof. In not a few cases the factors which so often lead to chronic alcoholism or inebriety play an important role in the precipitation of the acute attack. A consideration of these causes should always enter in the determination of the after treatment of the acute attack and the sole reason for omitting a presentation of them here is in order to avoid a repetition.

TREATMENT.

In acute alcoholic intoxication it is needless to say that all alcoholic drinks should be stopped and every effort made to eliminate promptly as much of the alcohol as possible. If the patient is seen early the stomach should be washed out, or emptied by means of emetics, such as apomorphine grain 1-8 hypodermatically, or a teaspoonful of the fluid-extract of ipecac in a large draught of tepid water.

Rapid elimination may also be favored by means of quickly acting saline aperients. These should be given in full doses in rather concentrated solution as they will in this manner not only facilitate elimination but also prevent further absorption. In instances where it is known that an enormous quantity of alcohol was taken the administration of a few minims of croton oil in a teaspoonful of olive oil is useful. Nature's process of elimination by means of diaphoresis may be augmented by hot packs, Russian or Turkish baths. The latter should be followed by a good massage or salt rub and the patient allowed to sleep for several hours. In acute, sthenic cases a dose of pilocarpine, grain 1-10, hypodermatically will produce a profuse diaphoresis which is beneficial.

When the patient is not quiet in two or three hours or suffers from insomnia the use of a hypnotic to produce a few hours sleep is of great importance. The choice of a hypnotic is a matter of no little moment. Drs. S. W. Rawson and G. D. Scott¹ after a study of 1-100 cases of alcoholism conclude that veronal is by far the safest hypnotic. They give it in large doses, 10 to 20 grains, in connection with teaspoonful doses of the fluidextract of ergot every four hours. Trional or sulphonal, in ten to fifteen grain doses, repeated at intervals of every two to four hours, are usually efficacious and safe. Tablespoonful doses of the elixir of paraldehyde also gives satisfactory results. Chloral hydrate is also reliable and may be combined with the bromides. Rawson and Scott show that morphine and hyosine in the treatment of the nervous disturbances of acute alcoholism are not only unreliable but also dangerous drugs to employ.

In order to sober up a patient who is only moderately intoxicated various drugs are recommended. Hennell² states that in acute alcoholism a half to a drachm of ammonium

chloride dissolved in water and given in one dose followed by a copious draught of water, will not only immediately counteract the effects of alcohol and sober up the patient quickly but will also prevent delirium and overcome the craving for alcoholic stimulation. With a limited experience the author has been unable to obtain any such results from this drug. Teaspoonful doses of the tincture of digitalis are also advised for the same purpose but beyond the emesis which follows the use of such doses no special results are apparent. A cold bath in connection with a full dose of caffeine citrate, three to five grains, will, after the stomach has been emptied give favorable results.

After an acute alcoholic spree the gastrointestinal tract is usually badly disordered and the nervous system disturbed. In some instances nausea or vomiting is troublesome. In such cases gastric sedatives, such as bismuth subnitrate, cerium oxalate, sodium bicarbonate, etc., may be given in peppermint, spearmint, creosote or chloroform water. If it seems necessary cocaine hydrochlorate may be given in association with the foregoing in doses of 1-6 to 1-4 grain. It is well to limit its use to cases in which the vomiting is very persistent or in which the vomiting has not been aggravated by dietetic errors. The diet should be limited, of a liquid and easily digested character if there is any gastric disturbance. Buttermilk, broths, bouillon, sweetmilk diluted with vichy or seltzer, and malted milk are usually well borne. Water may be allowed ad libitum. After the irritability of the stomach subsides it is usually advisable to give five to ten minim doses of the tincture of nux vomica in water three times a day. Many prefer to combine it with other stomachics, such as capsicum, ginger, cinnamon, gentian, or the compound tincture of cinchona. My personal choice is a mixture of ten minim each of tincture of nux vomica and dilute nitrohydrochloric acid in the elixir of glycerinated gentian or essence of pepsin as a vehicle. The latter should be given well diluted.

DELIRIUM TREMENS.

The acute delirious condition which not infrequently follows the excessive and prolonged use of alcoholic beverages is rather a grave type of alcoholism. Its mortality rate which varies from 10 to 20 per cent. is dependent principally upon concurrent disease conditions and the general vitality of the subject. Proper treatment also plays an important role.

In delirium tremens the patient loses all mental control, talks incessantly and incoherently, and has hallucinations which often give rise to intense horror and dread. Rawson and Scott state that here are two distinct

stages, first, a stage of insomnia, restlessness, tremor, hallucinations which are recognized as fictitious, and later a state of delirium with visual hallucinations which are uncorrected; in the second stage, the patient is very noisy, has hallucinations, which may be amusing, but are usually of a fearful character, a fever of 100 to 102 F., profuse perspiration, followed later by an exhaustion which is both muscular and circulatory.

The attack may follow an acute alcoholic debauch, or it may occur in inebriates as a result of an acute infectious disease, or a physical shock or injury. The sudden withdrawal of alcohol from an inebriate who has been accustomed to large quantities is not infrequently the cause of an attack. Ordinarily a certain amount of nervousness, irritability, tremor, insomnia and gastric disturbance precedes the onset of the delirium but occasionally it is ushered in with scarcely any premonitory symptoms.

TREATMENT. (PROPHYLACTIC).

Prompt and efficacious treatment of acute alcoholism will prevent the majority of attacks. In cases of acute illness in which there is a history of strong alcoholic addiction and in which there are any premonitory symptoms moderate amounts of alcohol should be given regularly and the use of sedatives should be commenced at the earliest possible moment. The same holds true in instances of injury. Again alcohol should never be abruptly withdrawn from the habitue. When an attack supervenes upon an acute alcoholic toxemia it is probably better to resort to eliminative measures rather than increasing the toxemia, although even in such instances some good authorities recommend that moderate amounts should be administered.

ACTIVE TREATMENT.

Rawson and Scott after a careful study of the results of the treatment conclude that all subjects in the inebriate or primary stage should be given large doses of hypnotics, preferably veronal, but never morphine or hyosine, also that whiskey be given at regular intervals and that ergot should be administered frequently in large doses either intramuscularly or by mouth. They advise teaspoonful doses of a reliable fluidextract every four hours. Lambert, another excellent authority, advises the use of 30 minim doses of Livingston's solution of ergot, hypodermatically every two to four hours:

Rx

Sterile Water zi
Extract of Ergot zi
Chloroform M iii
Chloretone gr iii

Mix and filter. Livingston's Solution.

Any reliable, aseptic preparation of ergot, may be given subcutaneously without danger, in from fifteen to thirty minim doses every three to four hours. This drug is particularly indicated on account of the circulatory weakness, the cerebral oedema or wet brain, which is an important part of the pathology, and also to prevent a pulmonary stasis and oedema. Such medication should be discontinued gradually and only after all symptoms have subsided.

Dennis' sums up the objects in the treatment as follows:

1. The elimination of toxæmia, by 10 grain doses of calomel with 20 grains of compound jalap powder, followed by salines. Supplemented later by high irrigations of the colon with saline solution. Petty urges the use of saline subcutaneously. According to personal views the use of salines is not safe unless the skin and kidneys are already actively eliminating.

2. The enforcement of sleep with sedatives and hypnotics.

3. Restraint of a mild, unnoticeable character, as a sheet under the bed clothes, in order to prevent self injury.

4. The maintenance of nutrition with appropriate amounts of milk and vichy, beef broth, buttermilk and predigested foods.

5. The alleviation of gastritis by lavage with alkaline or boric acid solutions.

6. The administration of cardiac stimulants, ergot, digitalis, strychnine, sparteine and whiskey.

7. Attention to atony of the bladder.

8. Cleansing of the teeth and the oral cavity.

Hydrotherapeutic measures, particularly hot packs or hot baths are often of great value in the sthenic types of cases. During convalescence massage, salt rubs, static electricity, and active and passive exercise are highly beneficial. If possible no case of delirium tremens should be discharged without some effort to break up the habit and to prevent recurrences which may prove fatal.

CHRONIC ALCOHOLISM—INEBRIETY.

Another highly important phase of alcoholism is presented by the habitual drunkard, the habitue who is more or less continually supersaturated. According to Dr. I. H. Neff, inebriety "is an expression of nervous weakness; used in its simplest sense, it could be called a psychoneurosis, many cases showing symptoms which are found in neurasthenic and allied conditions."

Dr. Petty, states, that it is not only a disease itself, but in many instances it springs from other diseases, and it is certain that other diseases grow out of it. The old English statutes while not classifying the habitual drunkard as an insane individual, state, that

oftentimes he is dangerous to himself or herself, or to others, and at times, is completely incapable of managing his or her affairs.

ETIOLOGY.

Petty holds that 80 per cent. of chronic alcoholics form the habit inadvertently, unintentionally and without any definite purpose in view. These, he regards, with proper assistance and treatment, as curable. In another class he places those individuals without character, drifting selfishly through the world, without rudder, compass or objective point. In a third class he includes those with congenital physical or mental defects. Petty makes a distinction between the habitual user of alcohol and the periodic or spree drinker, stating that the latter form an entirely different class which embraces four types of cases: 1. The dipsomaniac, real or symptomatic, who usually abstains for long periods and then yields to an obsession for, inordinate quantities. 2. Those cases due purely to a moral cowardice, in which the spree is sought as a refuge. 3. Those with an unstable nervous character and with bad environment and associates. 4. Those with an ever present, but usually, successfully resisted desire for alcohol with a constant bad environment. Some authorities endeavor to explain the acute deviation in certain dipsomaniacs in the nature of an epileptic attack.

Neff, in a study of over 800 cases, draws the following deductions as to the etiology: "The exciting causes are of a physical or psychic origin. Given a neurotic subject, crises may be precipitated by any marked departure from the ordinary routine of life or any psychic disturbance, or by any disturbance of organic or physical origin." "Inebriety," he states, "is prone to develop as a frank case, at the critical epoch of life, pubescence, or involution." He lays stress upon the heredity as a powerful predisposing factor. In over 40 per cent. of his cases he found a history of intemperance in one or both parents. In over 15 per cent. of the cases there was a history of defective ancestry, in the shape of insanity, neuropathy, drug addiction or tuberculosis.

Defective training and lack of character formation in childhood and early adolescence undoubtedly plays an important role in the formation of, and the inability to withstand, the habit. Faulty environments and improper associates, which oftentimes exist even in the home, are the determining factor in the early formation of the habit. The factor which is probably of greatest significance in the continuance of the habit lies not so much in extraneous matters as it does in the toxic condition of the system resulting from the abuse of alcohol and the disturbed

functions and metabolism, which result therefrom.

TREATMENT (PROPHYLACTIC).

Rigid regulation of the liquor traffic will probably accomplish more than the most ardent prohibitionist could ever hope for or desire. The treating evil should be abolished. The public should be educated in the dire consequences to the individual, the family and to society which so often result, directly or indirectly from the abuse of alcohol. The profession should emphasize, that alcohol, in no matter what form it is taken, is a drug rather than a beverage, and a rather dangerous drug, notwithstanding its free and prevalent usage. Many deductions might be made by reviewing various factors which have been set forth rather fully under the etiology but time does not permit a lengthy presentation of this phase of the subject.

ACTIVE TREATMENT.

Up to a certain point the treatment of all forms of alcoholism is alike and under this head we shall omit almost every measure of treatment which has already been mentioned. Two important factors must be constantly borne in mind in the management of the chronic alcoholic. First that the habitual demand is due mainly to the toxic condition of the system which has resulted from its abuse, and secondly that unless all of the ordinary functions, particularly those of nutrition and sleep are normal, it will be impossible to prevent relapses. Unless the patient is placed in a shape to withstand his customary amount of exertion and strain the treatment will be of little avail.

In the vast majority of instances institutional care is essential for a cure. Private institutions often obtain splendid and lasting results, but in many cases the patient can not be kept for a sufficient time in order to prevent subsequent relapses. As the formation of the habit is usually a matter of many years it follows that the active cooperation of the physician and the patient is necessary for a considerable time. In private practice, by insisting that the patient remain under the physician's care and attention for six months to a year he may occasionally be completely cured.

The state care of inebriates is a matter which has been sadly neglected by not only our own Commonwealth but by the majority of the states in the Union. That the expense of proper provisions for the care and treatment of inebriates would be more than saved within a few years by a lessening in the number of unfortunates who today overcrowd our jails, workhouses, penitentiaries, insane and other asylums, can scarcely be gainsaid. The saving to the family and to future generations

would also justify such expenditures. As physicians, awake to the importance of cause and effect, and cognizant of the obligation we owe our fellow men, we should strive to bring such matters before those at the helm of our state.

In closing, the following points on the state care of inebriates are quoted from an article by Dr. Daniel Crosby⁷: 1. That from 50 to 60 per cent. of all drug and alcohol habits are curable permanently. 2. Every state in this country is fully warranted in giving more attention to alcoholic habits than its present statutes provide. 3. That special institutions governed by a board, a medical staff and attendants, selected solely on account of their fitness, should be provided for the treatment of inebriates. 4. That inebriates should be committed to these institutions for from six months to three years on the indeterminate sentence plan, and recommitted as necessary. 5. That ample means, equipment, and provisions for occupation, etc., should be placed at the disposal of the staff. 6. That politics should not enter into the management of these institutions.

DISCUSSION.

W. F. Boggess: Dr. O'Connor has given us a very practical paper and he has covered the management of these cases pretty fully. While it is in my mind, I would like to emphasize one fact that is not generally believed; namely, that 50 to 60 per cent. of all inebriates are curable. By that I mean that they are permanently curable; that if we will correct the nervous condition and get the man away from his alcohol, he has enough manhood and willpower left to remain permanently cured. It seems to me that there is no case of inebriacy that we should look upon as incurable. We never know what we can do with these patients—how much manhood is left in them. It should be looked upon as a disease condition, and institutional management is unquestionably the safest and best. It is a reflection upon American civilization, as Dr. O'Connor truthfully said, that so few of our states maintain hospitals for inebriates, and that the laws of some states permit them to be sent to asylums for the insane. The state asylum is no place for inebriates, unless it has in connection with it a psychopathic hospital, thus making it an institution for the care of inebriates as well as the insane.

I do not think there is any drug so little understood by the profession, with respect to its

pathologic and toxic effects, as alcohol; they are more inclined to look upon it as a palatable-pleasing liquid, made to have a good time with, and overlook the fact that alcohol is a very toxic agent. It is in no sense a food; it is a poison. Alcohol is a drug, a therapeutic agent of considerable value when intelligently used, but I do not believe there is a drug that is more frequently unintelligently used than alcohol. Take, for instance, its effect upon the stomach. Put a few drops of alcohol upon the tongue, and immediately there is a flow of gastric juice, a congestion of the mucosa and increased gastric secretion. If we give a patient a teaspoonful of cognac brandy before each meal, it increases, not only the appetite, but the digestion, but if we give him a little more alcohol we interfere with proteolysis and inhibit digestion. It will give him a false appetite, but digestion is inhibited. The effect of alcohol upon the liver cells is well known. At first it stimulates the liver cells and increases the flow of bile, but in a short time it causes fatty degeneration of the liver cells, increases interstitial hyperplasia, and produces cirrhosis of the liver. It also damages the kidney, although not so quickly, because, by the time it reaches the kidney it is so diluted that the effect upon it is very much less than upon the liver.

The effect of alcohol upon the nervous system is that of a depressant. It is not a stimulant, except possibly in small quantities and for a trifling period. It is a depressant because it depresses the inhibitory and controlling functions of the brain. Although the subject feels stimulated and warmed by it, the central nervous system is really depressed, and it has a toxic effect upon the brain.

There are certain types of fevers in which alcohol is a most excellent remedy. The oxidation of the alcohol tends to prevent the wearing and burning of the tissues in the body; therefore, in certain types of asthenic typhoid fever, alcohol does good in that it prevents tissue metamorphosis. Again, in certain types of pneumonia, I believe that alcohol dilates the superficial capillaries, throwing the blood to the surface, and does good in that way.

So, I think there are certain cases where alcohol can be, and should be, used as a remedy. It was never intended for a beverage, and it is poisonous to the tissues, just as strychnin, cocaine, and other poisonous drugs are.

In regard to the treatment of these cases, there is one simple remedy in acute alcoholism that I believe the essayist overlooked; that is, table-spoonful doses, every hour, of freshly made liq. ammonii acetate. In delirium tremens this is one of the very best remedies we have at our command.

Having read, some years ago, in one of the journals, a statement to the effect that thyroid extract was beneficial in certain cases of chronic alcoholism, I have tried it in one or two

cases, and it is unquestionably of great benefit.

When it comes to quieting a patient with delirium tremens, I think the administration of hyoscin, with a little morphin and full doses of atropin, is of value. I give these patients 1-30 gr. of strychnia and 1-150 gr. of atropin, hypodermically, every four hours, and it unquestionably carries them over the serious shock, through the crisis, and they seem to get well a little more quickly.

I long ago discontinued the use of chloral hydrate in these cases. During my hospital experience of thirty years as staff physician, I know that patients have been killed by the use of chloral and the old bromidia. I have frequently given digitalis in teaspoonful doses, and I think veronal in solution is one of the best of hypnotics.

As to the withdrawal of alcohol, it has always been a question in my mind, in delirium tremens and in chronic alcoholics as well, as to how rapidly alcohol should be withdrawn. Should we take it away at once or should we take it away gradually? I think this is a question that must be settled by a study of the individual case and the condition with which we are dealing.

Milton Board: Not longer ago than twenty-five years the medical profession, and the laity as well, were inclined to look upon two disease conditions with a spirit of levity. I refer to gonorrhea and the question under discussion—alcoholism. A good many years ago the seriousness of gonorrhea was recognized by the profession, and they have since been doing their part in educating the public to beware of its dangers. But, with respect to alcoholism, the medical profession has either not recognized the seriousness of this condition; or, if they have recognized it, they have not done their part in educating the public to prevent it, for here, as in most fields, preventive medicine is our greatest hope.

I wish to say a few words, briefly touching upon some of the points brought out by the essayist, beginning with the acute condition. I want to take issue with him here and now as to the advisability of administering ipecacuanha, or anything else that will upset the stomach, in sobering a man with an acute alcoholism. When that man is comparatively sober he is going to need a good digestive system; in some cases they need it badly. Hence, the custom of making a man, who is suffering from acute alcoholism, sick, is bad practice. It does not hasten getting him sober to any material degree, and it does interfere very much with getting a man on his feet and about his business.

Now, in regard to sedatives, you cannot go to see a patient suffering from acute alcoholism and handle him as you would a sane man. Not long ago I was called to see one of Dr. O'Connor's patients. I found him drunk, and he was an Irishman and had a head of his own. I prescribed some remedies and went back the next day.

He had not taken any of the medicine and had not done anything except what he pleased to do; so calling a cab, I persuaded and forced him to get into it and go home with me, and there I administered the remedies necessary to relieve the man. You cannot very well do that except in a place where you can control the patient.

In making a man sober who is drunk, the most important part of the treatment is to get him to sleep. From three to six hours' sleep is worth everything else so far as sobering the individual is concerned. How are we to bring that about? If the patient is in an institution, begin with a Turkish bath; if he is in a private home a hot bath will do almost as well, but when you give a hot bath, give a **hot bath**; give it for an hour, or two hours. Keep the man in the bath until he gets sleepy. I have seen patients suffering from acute mania, which is a toxic condition as is acute alcoholism, kept in hot water for two weeks with splendid results. So, in dealing with these cases and giving baths, no matter whether it is a Turkish bath in an institution or a plain hot bath in a private home, keep the patient in it long enough to accomplish the result desired.

I like to use hyoscin in these cases, generally 1-150 gr., sometimes 1-200, sometimes 1-100, depending upon the condition of the patient's heart. In a strong, sthenic case, with a good heart, I have no hesitancy in giving 1-100 gr. of hyoscin. However, it is a drug to be cautious with, especially if there is danger of delirium tremens; but combined with heroin in 1-16 to 1-24 gr., it is a remedy that will bring about sleep, and that is what we want to do. Therefore, our routine treatment of these cases is to first put the patient in a Turkish bath and keep him there a long time, then put him to bed, and almost invariably we give an injection of hyoscin in some quantity, combined with heroin, never using morphine. By this means we seldom ever fail to bring about four to six hours' sleep, and when that sleep is over we have a tractable patient, half sober, who will take a drink of buttermilk of a dose of medicine if we want him to.

As the essayist mentioned, we sometimes have very serious stomach trouble to contend with in these cases, and vomiting is very persistent. Hot water, alternated with ice water, (of which the former is the more valuable), with bismuth, and, frequently, cocaine, has a very happy effect in controlling this symptom.

In the treatment of alcoholic mania or delirium tremens, I do not think it is well to withdraw the alcohol at once. I agree with the essayist that alcohol should be continued for a time. I like to give it in the form of egg-nog, because there we have it in the form of a food and we also get the stimulating effect of the poison that brought about the condition. These patients need to be fed.

The essayist spoke of mild restraint. We

must remember that we usually have most intractable fellows to deal with, and if we are going to employ any restraint at all we must use enough to accomplish our purpose. It has been determined and now goes without question that in alcoholism we have a disease condition; we have a neurosis. Furthermore, in the vast majority of instances, it is an hereditary neurosis. That is to say, the tendency to the habit is markedly transmissible from father to son, from grandfather to grandchild, and so on. In many instances the disease is curable. The ideal institution for the cure of alcoholism should be located in the country, and should be under state control, because, as a rule, individuals cannot be kept in private institutions long enough to accomplish ideal results. Do not understand me to say that much cannot be done for these cases in private institutions, but I am speaking of the **cure** of the condition. If we had a state institution to which these cases could be committed by the court, for a stated term, many of them could be cured.

Virgil E. Simpson: I do not believe in the dietum that, because of injudicious use of a certain agent we are in danger of establishing a craving for that agent on the part of the individual, its use as a remedial measure is not justified. The value of alcohol depends upon its local action, its influence on the control nervous apparatus and finally, its food availability. If we will analyze the pharmacological action of alcohol, or carry it further, in to its toxicological influence, which is simply a multiplication of its pharmacological effects, it will not be difficult to more clearly understand the conditions that confront us when we attempt to bring about a so-called cure of chronic alcoholism. Alcohol, in common with many other derivatives of the methane series has the property of combining with the lipid substances in the nerve cells; in other words, the lecithin and cholesterin which are found in the cells are partially dissolved by alcohol; their relationships, chemically, are altered; and their influence, so far as the chemical and physiological action of that particular cell is concerned, thereby changed. This is common. I say, with all the hydrocarbon group. Now, when the amount of alcohol is continued, or the percentage of concentration increased beyond the pharmacological limitation, the cells materially change their chemical makeup, which can be demonstrated by staining the cells, which show a diffuse coloration of Nissel's granules instead of the grouping in highly colored spots and areas as found in normal cells. In addition to this, the dendrites are also affected by the action of alcohol, in that they shrink, become much shorter, and nodular enlargements are found on many of them. When the use of alcohol is continued, in excessive amount and over a long period of time, there are many organs that become seriously involved, and pathological

changes obtain which no measures we possess can alter or replace in any reasonable length of time.

The influence of heredity upon alcoholism is a very interesting question. It is stated that when alcohol exists in the body in higher concentration than six parts in one thousand, death is inevitable, and that whatever concentration obtains in the mother's blood during the pregnant state, the same degree of concentration will obtain in the foetal blood. I do not believe that the taste for alcohol is directly hereditary. It is just as impossible for my mind to conceive that a child born of an inebriate mother or father will, of necessity, develop an uncontrollable desire for alcohol as it is that a child born of a morphin habitue will develop a taste or desire for morphin. Certain it is, however, that the child of an alcoholic father or mother will inherit an unstable nervous system, one that does not maintain its normal equilibrium, that responds unduly to the ordinary wear and tear of existence, that does not possess within itself sufficient vitality to give to the body the tone and vigor that is required in the ordinary performance of body function. With this defective condition throughout the central nervous system, this lack of normal equilibrium, it is perfectly possible that the child, in the environment in which it is likely to live, may become addicted to the use of alcohol, or anything else that is equally available.

Acute alcoholism requires a very short period of treatment, and most of these cases recover; but with respect to the management of the chronic alcoholic, I am of the opinion that any attempt to manage a case of this sort in a private home, is absolutely futile in a great percentage of cases. We must remember that we have to deal with an individual who is irresponsible, whose morals have materially deteriorated, who has lost a normal conception of his responsibilities and that fine appreciation of the relationship existing between himself and his fellow-man; who has lost all appreciation of the duties and obligations he owes to his own family. When we remember that we are dealing with a man so morally perverted that he will stoop to dishonor and falsehood in other things, it is but reasonable to believe that he will be dishonest with reference to the continuation of a habit of this sort. We cannot depend upon the veracity of these cases any more than upon that of the cocaine or morphin habitue, and unless the patient can be kept under the observation of a thoroughly reliable and dependable nurse, day and night, we may as well dismiss the case with the first visit, because we will meet with an unsatisfactory result.

So far as the use of remedial agents is concerned, I cannot see any pharmacological ground for the administration of paraldehyde. It is too closely related, chemically and pharmacological-

ly, with the action of alcohol to permit us to use it.

I am also averse to the administration, under ordinary conditions, of chloral hydrate, because it is so depressing to the circulatory apparatus. Vasomotor paralysis, both central and peripheral, may obtain after its administration—a condition too characteristic of the drug we are attempting to combat. Neither can I believe that it is good treatment to administer such drugs as trional and sulphonal. These drugs are but sparingly soluble and are absorbed very slowly. The stomach is still in a state of rebellion and, as a consequence, we cannot introduce drugs of this sort into the stomach and expect to produce sleep in anything like a reasonable length of time. A better way to secure hypnosis is by means of the hypodermic needle, and hyoscin is one of the best agents that can be used in this condition.

B. J. O'Connor, (Closing): In closing this discussion it will be impossible for me to touch upon all of the points that have been brought out.

In regard to the use of hyoscin, I do not know whether it has been due to the variability of the preparation I have used or to some unexplainable personal peculiarity, but my experience with it has been so extremely variable that I always hesitate to use it. In some cases, in my hands, instead of producing sleep, it will produce the wildest type of mania, given in exactly the same dosage of exactly the same preparation. Neither morphin nor hyoscin are primarily hypnotics; they relieve pain and produce dullness, and the hypnotic effect is a secondary one.

The statement made in the paper in regard to the danger of using morphin and hyoscin was quoted from Rawson and Scott, who cite 1109 cases which came under their observation in the Massachusetts Hospital for the Treatment of Alcoholics, which were compared with reports from the Massachusetts General Hospital, where quite a large series of cases had been treated, and also with reports of the Cook County Hospital in Chicago. It is only by gathering and comparing such statistics that we can form a reliable opinion as to the value of certain drugs.

Indications for Decapsulation of the Kidney.

—Lehmann reports three cases of chronic nephritis in which great benefit was derived from decapsulation, although the nephritic process itself did not seem permanently influenced. The general health, however, was much improved. He regards it as a life-saving measure in most forms of oliguria or anuria, especially with uremia in the course of acute nephritis; in this case it may have a favorable influence on the nephritis itself. It is indicated for uremia with chronic nephritis only when the trouble is an acute exacerbation of the chronic diseases and kidneys are still functionally capable. He cites instances of the various types.

THE FUTURE PREVENTIVE MEDICINE.*

By JOHN N. HURTY,

(STATE HEALTH COMMISSIONER OF INDIANA.)

For one hundred and fifty years yellow fever plagued Havana. Men were ignorant, and therefore, must suffer. We frantically tried to stay by quarantine. We thought that somehow its infection was carried in clothing. He was a pariah who had yellow fever and who had come from a zone where it existed. People held their breath when a yellow fever patient was in sight, and would as soon handle red hot iron. This was ignorance. The mosquito, the carrier of the infection, was disregarded, and when the world was told by the discoverer that the mosquito was the means of distribution it scoffed the truth and derided the discoverer of the truth. To prevent the introduction of yellow fever into this country, a special quarantine was maintained from the Rio Grande along the gulf coast, around Florida and up the Atlantic to Charleston, costing annually hundreds of thousands of dollars and not keeping out a single case of yellow fever. Sulphur was burned by tons and the gas forced into ships, ruining machinery, cargo and furnishings. Travelers were delayed in quarantine camps, and commerce was halted. All this resulted from ignorance. We did not know and understand. Dr. Carlos Finley, with observation powers superior to all who had gone before, perceived that the infection of yellow fever was not carried in clothing and by fomites, but was carried by mosquitoes and he so announced.

The darts of ridicule flew at him from every quarter. Editorials in lay and scientific prints showed how foolish were his contentions. Paraphrased and cartoonists had their day of ridiculing the discovery of a truth, and amidst all of these manifestations of ignorance and conceit, Dr. Finley stood alone, calm and confident, and now he has his day.

Truth is born in pain. The yellow fever quarantine is now a thing of the past, and we smile sadly at mention of it.

THE FUTURE.

What does the future hold for the prevention of other diseases? Therapeutics have gained many victories, but to hygiene belongs, without doubt, the place of honor in modern medicine. How completely therapeutics failed with yellow fever?—and how complete was the victor of hygiene? Was ever a case of typhoid fever cured with medicine? Who can positively and unequivocally say yes? The long time universal acceptance of the adage—

*Read by invitation before the Jefferson County Medical Society.

"An ounce of prevention is worth a pound of cure," is not strange, for it is an obvious truth. It is however, passing strange, that a practical people go little further than to acknowledge this truth and halt at its thorough practical application. A medicine to cure yellow fever is no longer sought for. Therapeutics carries no burden of investigation in that line, and to find a cure for cholera, no longer concerns that branch of medicine. We know there are two ways for fighting disease. We may destroy and keep the germ out of our bodies, and we may produce immunity. We now practice the first way with yellow fever and cholera, and the second with smallpox. It seems likely that only in comparatively a few diseases, will their hygiene consist in the destruction of the pathogenic microbes outside of the human body. It is not now the ideal of hygienists to preserve man from all contact with the germ of infection. Often we find the living body remains well in spite of its containing disease germs. When Loeffler first found diphtheria bacilli in the throat of a healthy child, doubts arose in his mind as to the etiologic role of his microbe.

Before that time hygienists believed that the infectious germs were only present when disease existed. Now, it is known that a man may be the host of diphtheria, typhoid, pneumonia and other germs without necessarily developing the corresponding diseases. It has been proved to be possible to introduce quantities of tetanus spores into the body of a guinea pig without the animal, which is exceedingly prone to develop tetanus, acquiring the disease. But Vincent has shown that by starving the animal, worrying it, or exposing it is too high a temperature—its resistance can be overcome and tetanus produced. Such results could not fail to influence practical hygiene.

Until rather lately it was believed that all typhoid infection was water borne, but now we know that the disease is contagious as well as infectious, and also that flies and very likely other insects carry it. Some hygienists even contend that "typhoid fever" is more frequently transmitted by contact than in any other way. In 1904, five cases of clinical typhoid at the Indiana Soldiers' Home, at Lafayette; the water supply from deep wells was faultless, the sewerage of the institution was perfect, and the cleanliness also perfect. The questions were: Where did the infection come from? and how many mild cases were there? Through laboratory tests by the Widal method and by bacteriological examinations of feces and urine, sixty-eight cases were discovered. Some of the unrecognized cases were diagnosed as malaria, some as obscure heart trouble, some as debility and others as stomach and bowel trouble. Final-

ly, four of the laundry force were taken down, also their nurses and two of the doctors.

Three months before, a son of the Commandant had come from college with typhoid fever and had almost succumbed. All excreta had been disposed of through the sewer and fly carriage was impossible, and so only one other method of transmission, namely contact, was possible. So the doctor in his rounds was observed and as he failed to wash his hands after handling the typhoid patients and passed on to others (it was supposed he was the carrying agent. He was, therefore, asked if he had handled the first case in this same way and he said he had. Eventually he came down and very nearly died. The washings of the door knobs of the doors of the typhoid patients' room all yielded colon bacilli.

The future hygiene will certainly require most careful department on the part of doctors and nurses. German medical literature tells of a woman who owned a bakery in Strassburg, and it was observed that her employees were constantly being attacked with typhoid fever. The bakery was very clean and passed the rigid German sanitary inspections, and so the authorities, as the care of the sick persons was upon the city and a public expense, made individual studies. It was found the proprietress had had typhoid fever ten years before, and that her urine and feces were teeming with virulent typhoid germs. She prepared all of the food for her employees and all used the same toilet closet. And so again the future hygiene will look further than the water supply for sources of typhoid infection.

At the conference of the water works officials with the State Board of Health recently at Indianapolis, the president of a certain city water company told of a case of typhoid fever next to his own house, and he learned by inquiry that the doctor had not given the slightest directions concerning the disinfection of the discharges. And furthermore, the said doctor said he never had given any such directions in all his years of practice! The water works president added, "What shall we do to protect ourselves against certain members of the medical profession?" Others present told of like experiences, and I mention the matter here that we may be reminded that the dirty, negligent doctor is not an honor to medical science and that the eyes of the public are open.

The future hygiene will also carefully immunize in all the phases, and especially the point brought out by Shiga, the eminent Japanese bacteriologist, who has shown us that quite all forms of diarrhea are due to the dysentery bacillus. In a word, that all continued infectious diarrheas, whether mild or severe, are really dysentery. Twelve years

after Shiga had had typhoid fever he examined his blood and found it absolutely free from agglutinating or sensitizing substances, yet he lived unattacked when he unquestionably, in an epidemic of the disease, had taken in the infection. Evidently then, immunity does not depend upon the presence in the blood of protecting substances, for many other instances like that of Shiga's are known. And again, patients have been known to have a relapse when the blood contained large quantities of agglutinating and sensitizing substances. For these reasons, Widal, the inventor of the sero-diagnostic method of typhoid fever, has always contended that those properties are not indicators of a refractory state of the body. After having proved that his serum contained no agglutin Shiga injected himself subcutaneously with liquid products of the bacillus typhosus. He found that already after eight days the agglutinating power of his serum was manifest in a dilution of 1 in 640, and the sensitizing substances showed a corresponding increase in the same time. The serum of another person who was injected with the same substance, showed an agglutinating power only in a dilution of 1 to 80 after the same interval. This great difference—for Shiga's serum agglutinated eight times more strongly than the other man's—may be explained by the fact that the Japanese bacteriologist had had typhoid, whilst his colleague had never suffered from the malady. Shiga's immunity, therefore, consisted in a vital modification of his cellular elements.

The future hygiene will consider what modification may be practiced. In his researches on acquired immunity towards the cholera vibrio, R. Pfeiffer was much astonished to see his vaccinated guinea pigs dying in spite of the presence of large quantities of sensitizing substances in their body liquids. These animals died of the infection caused by the cholera vibrio. Now this result can readily be produced by paralyzing for a certain time the activity of the white blood cells.

Cantacuzene succeeded in killing, by vibrionic infection, even highly immunized guinea pigs by preliminary injection of small quantities of morphine. Thus it was sufficient simply to retard the phagocytic action by a drug in order to make the animals lose their immunity and to render them an easy prey to the cholera germs. Medication, therefore, is dangerous, and must be practiced only in the light of immunity experimentation. Preventative may come to mean, in part, the prevention of the giving of medicine. For, if *only* the phagocytes can fight off invading disease germs, and if some medicines hinder or damage the phagocytes, then it follows that said medicines should not be given, at least at times. This is not at all strange or new, for

we have always known that the very best medicines are at times contraindicated.

ALCOHOL FAVORS DISEASE.

More medicines than morphine are adverse to phagocytic action, and among them is alcohol. It is well known that persons who indulge too freely in alcohol show far less resistance to infectious diseases, especially to pneumonia, than abstemious individuals. The vaccinations against hydrophobia carried out on persons bitten by rabid dogs are rarely failures; but when the person is an alcoholic they are generally failures. Delearde found that rabbits to which he administered alcohol in the course of immunization against anthrax, died of the disease, while the control animals, which were not given alcohol, did not die. And Abbott has confirmed these experiences by proving that animals, if subjected to the influence of alcohol, become more sensitive to the harmful effects of certain microbes, such as streptococci, staphylococci and bacterium coli. Latvian administered alcohol to rabbits for several weeks and then injected them with a small dose of the first vaccine of anthrax. Six animals thus treated died after a more or less prolonged illness, all of these contained anthrax bacilli in their blood and organs. Of four control rabbits which received the same dose of the same vaccine, but to which no alcohol had been administered, only one died, and the other three enjoyed perfect health. Experiments by others have shown clearly that alcohol inhibits the activity of the phagocytes, and if their health and forcefulness against invading germs is lowered, defense must be feeble. As a logical consequence of the experiments of the weakening of immunity under the influence of alcohol, it plainly appears that this substance is contraindicated in the treatment of infectious diseases.

The future hygiene will teach temperance from a truly scientific standpoint.

THE HYGIENE OF THE ALIMENTARY CANAL.

Metchinkoff has an exhaustive essay upon "The Hygiene of the Alimentary Canal," from which I draw freely. It is safe to say that with a normal alimentary canal acting normally, health and resistance to disease will quite always prevail. It is now proven without doubt that microbes can penetrate into the blood by way of the intestine. Ravenel has shown that dogs fed on butter containing virulent tubercle bacilli exhibited the first and only lesion, not in the intestine, but in the lungs, or other organs, principally, however, the lungs. No lesion occurring in the intestine itself except in a few instances. This happens when the intestine is believed to be intact, but far more freely when there is constipation, diarrhea, or intestinal indigestion.

After extra hearty meals, too, and after gorging especially, microbes may penetrate more freely through the intestinal walls and find their way to organs and attack them. Dilatation may therefore be conducive to infection. The future hygiene then will insist upon keeping the intestinal canal in normal condition. In the Pasteur Institute, where great experience in the methods of preparation of therapeutic serums has been gained, they have for years made it a standing rule to bleed a horse after a meal, because under the conditions the development of microbes may take place in the serum, even if it has been obtained under the strictest aseptic precautions. There they say, "An animal should always be kept fasting before bled, if it is to furnish a sterile serum." This is now done in all serum laboratories.

The greatest liability of the body to microbial invasion after a meal is probably due in part to the fact that the food is plentifully supplied with them. For instance, a glass of milk, will contain untold millions and very frequently quantities of them are pathogenic. The more bullets in the air the more the likelihood of being hit. If digestion is vigorous, it would seem there would be lessened chances of the organisms introduced with food from penetrating the intestinal walls; but digestion, even in animals, is not infrequently more or less impaired. Besides, in eating, we almost always take in some rough particles, a minute piece of bone or oyster shell, a grain of sand, berry seed, or scratching particles of some kind. These may wound the mucous lining of the intestine as they occasionally do that of the mouth, and thus make a portal of entry for microbes into the tissues beyond. Eating, therefore, is an act not unattended with danger, just as walking in a crowded street is dangerous. In large cities, a number of people are injured or killed daily in the streets or in buildings, when simply pursuing their ordinary life, the life they have followed for years. This danger every one recognizes, and takes precautions accordingly. In eating, it is true we recognize the danger of poisons; and toxin poisoning is not of infrequent occurrence. But, until lately, it has not plainly appeared and appreciated that we take our health and our lives in our hands when we sit down to eat. The future hygiene will emphasize from a laboratory standpoint, from a highly scientific basis what is already taught on general principles,—that food must be clean, always well cooked, slowly taken, and well, very well, masticated. It must be taken, too, in moderate quantities; for dilatation of the intestinal tract, the stretching of membranes, favors the passage through them of germ enemies.

The so-called digestive leucocytosis is deep-

ly interesting. Many observers have found that in man, as well as in several other mammals, the number of white blood cells increase sometime after meals. There are differences of opinion as to the explanation of this phenomenon. Nicholas and Lot have made investigations of this matter and have established the fact that the number of white blood cells rises after a meal, especially if the food be raw beef. Even in rabbits, after feeding on cabbage and bread, the white cells increase. In one series of experiments the greatest number of leucocytes was found one hour and a half after the meal. What is the reason for the analogy with the leucocytosis of disease, an analogy so striking that one might be tempted to inquire whether the digestion of food is not also a kind of infection?

The fact of the matter is, a certain number of microbes penetrate through the intestine, and find their way into the circulation, and it being the business of the leucocytes to evict the intruders they dutifully rally to their work. What will future investigation discover in connection with digestive leucocytosis? And what bearing will it have upon dietetics?

The theory of von Behring—that tuberculosis in man is caused by the ingestion of Koch's bacilli in early childhood, has much solid ground to stand upon and has lately given rise to a great deal of research work on the mode of entry of microbes into the inner organs and the blood by way of the intestine.

Recently, Calmetti and Guerin, as well as Vallee, have published much new data supporting the contention. Whilst the direct introduction of tubercle bacilli into the trachea of calves was, in Vallee's experiments, followed by slight lesions, the absorption of the same bacilli by way of intestine produced a severe tuberculosis of the lungs.

Not all pathogenic microbes show so great a power of invading the body from the intestine as tubercle bacilli. Thus, it is most difficult to cause anthrax in guinea pig by making them swallow the virus. But the slightest lesion of the intestinal wall is sufficient to enable the swallowed bacilli to enter into the body and to cause fatal infection. Although there still remain several open questions with regard to the mode of infection by way of the intestine, as no doubt remains as to the very great importance of this gate of entry. The entirety of the results which have been accumulated by science, prove that the intestinal wall is worthy of being made the subject of most careful hygienic consideration. One recently acquired knowledge of infectious diseases has shown that many of those which were formerly attributed to special miasmata circulating in the atmosphere, in reality originate from wounds caused by insects. Especially to English investigators, science

and humanity are indebted for this fundamental idea. Following the memorable discoveries of Manson on the role of mosquitoes in the transmission of filariae, Bruce demonstrated that the disease called magana is caused by a trypanosome which is inoculated through the tse-tse fly. Since then a large series of Arthropoda have been recognized as dangerous intermediaries which transmit to man and to animals, the virus of human plague, of malarial fever, yellow fever, relapsing fever, sleeping-sickness, Texas fever, spirillosis of fowls, etc. Most frequently diptera, such as mosquitoes and flies are the transmitting agents. In bubonic plague, fleas play the role of inoculators, in relapsing fever, bugs and ticks fulfill their similar functions. Within the last few years insects and arachnidae have attracted the most interest from medical men and naturalists, and whilst formerly only a few amateurs devoted themselves to the detailed study of the diptera and arachnidae, these classes have nowadays, become the object of most assiduous study to a large number of scientists. As a result of these investigations, an elaborate system of hygienic measures has been worked out, which consist in endeavoring to avoid and to destroy mosquitoes, rats carrying fleas, flies, head-bugs, etc. A most simple hygienic precaution was recommended by Koeh against African relapsing fever. According to him, one need only avoid the huts which are infested with ticks and sleep at a distance from the road of the caravans in order to prevent having this disease. How simple then, is the hygiene of African fever.

To the diseases originating from the bites of arthropoda correspond to the diseases originating from wounds of the intestine and caused by entozoa, mainly intestinal worms.

Formerly, great attention was given to these parasites, to which were attributed all sorts of local and general maladies. In therapeutic systems of fifty or sixty years ago, a great deal was said for vermifugal remedies, by which many intestinal troubles and even certain nervous disorders were believed to have been cured. Since that time, the parasitic worms have been removed to a very different plane, and they have been nearly forgotten in favor of the microbes, to which is assigned the place of honor in medicine. The worms were so often found living quietly in the intestine, and their hosts were found not perceptibly suffering through them, that physicians had become accustomed to consider them almost, or quite, inoffensive. And yet this opinion is by no means justified. True, an intestinal worm may not impair health in any way, just as many mosquitoes, fleas and ticks may prick men and animals without causing anything more than a transitory and not painful itch-

ing. But on the other hand, it is equally certain that the bites of intestinal worms may cause as much evil as the pricks of arthropoda carrying pathogenic microbes.

Many examples and observations could be cited which supply a broad basis for concluding that intestinal worms play no inconsiderable part in the etiology of disease of the alimentary tract and of those maladies which are inoculated through that tract. The success which frequently results from vermifugal treatment in persons suffering from appendicitis, pointed to the importance of the entozoa in this disease. It is more than probable that a campaign against intestinal parasites, which would be conducted on similar lines to the war now waged against mosquitoes and other microbe-carrying insects, would be a move which would produce marked results in prophylaxis.

As parasites of all kinds, microscopical and macroscopical, from the minute bacillus typhosus to taenia solium twelve feet long, find entrance to our bodies in food and drink, it behooves us as reasoning creatures, to take care of our food. We must all agree with Metchnikoff, that raw foods are unhygienic.

Hygiene measures to prevent the introduction of disease by way of the alimentary canal, must keep vigilant watch over everything that enters the mouth. All foods, including water and milk, vegetables and fruits, should be submitted to a boiling temperature for at least five minutes, for butter and milk and for other articles a sufficient time to thoroughly cook them. In addition to this, cleanliness must separate us from our excreta, by which I mean that all sewage must be disposed of in a sanitary way and everything possible be done to prevent the re-introduction of our excrement into our alimentary canals.

Let all these things be done by all persons all of the time, and Pasteur's grand inspired message, "It is within the power of man to banish all parasitic diseases from the earth," would in great part be realized.

Serotherapy of Tuberculosis to Date.—Piel comments on the increasing vogue of serotherapy in tuberculosis during the last eight or ten years but adds that opinions are still divided as to the dosage, and especially the dosage at various ages. He reviews the history of serotherapy, especially of the maragliano, Nephroschney and Marmorek preparations. He remarks in conclusion that we have not made much advance in serotherapy after all in the last twenty years, and it is possible that we are on the wrong road, but that the results to date justify further trials, keeping watch over the outcome for years and always with a scientifically critical mind.

CLINICAL CASES.

REPORTS OF CASES.

By C. B. SPALDING, Louisville.

CASE I.—PYONEPHROSIS.

I saw this case with Dr. Bushong, of Tompkinsville.

Patient, female; age 24; white; married; weight about 100 pounds; gave birth to a child about two weeks before this trouble came on. She made a perfect recovery from the birth of the child, got up and went to the county fair. She came home complaining of pains in the lower abdomen. These pains continued and became so severe as to require the woman to go to bed. She began to run a temperature ranging from normal at some times to as high as 103 at other times; no regularity in the temperature scale. Pulse around 120. The pains began to subside in the lower abdomen and to extend upward on the left side, finally locating themselves along the border of the left costal cartilage. Abdomen distended but not rigid. Examination showed complete subsidence of any symptoms which might have indicated pelvic trouble, all the symptoms being referable to a mass under the border of the ribs on the left side. The fact that the temperature was normal at some periods of the day and high at other times indicated to me that the condition must be such as would admit of partial drainage of the supposed abscess cavity, and the lack of rigidity suggested that this condition was extra-peritoneal. However, I told the doctors I could not be certain that the kidney was the organ at fault, and would make a puncture in the left rectus muscle in an effort to verify the diagnosis. This we did, Dr. Bushong assisting, and readily made out that the mass was the kidney. The wound was promptly repaired, the patient turned on her side, and the kidney taken out from behind.

The kidney was very large—about the size of a foetal head, filling the entire left upper quadrant of the abdomen, with a very short pedicle, making it exceedingly difficult to amputate without rupturing the sac. However, we succeeded in getting it out without rupture and without any hemorrhage except from the sac wall. The pedicle was tied with chromocized catgut, No. 2, and the clamp

left on. The wound was closed with drainage and the woman put to bed with a pulse of about 140. Dr. Bushong 'phoned me two days later that the patient was holding her own, and at the end of three weeks she was sitting up, all the fever having disappeared and the wound having healed. I heard from Dr. Bushong about the first of February, and he reported that the patient weighed ten pounds more than she ever had in her life and was perfectly well.

Pathological examination, made by Dr. E. S. Allen, showed no evidence of tubercle bacilli.

CASE II.—GENU VALGUM.

Patient, a female colored child, aged 7 years, with a most exaggerated condition, as cut No. 1 will show.

Operation performed August 3rd, 1911, consisting of breaking the bones just below the knees, finding it necessary to break both fibula and tibia by means of the chisel. Each leg was then twisted so that it would be as nearly as possible in a straight line, and a plaster cast applied from the thigh down. The first change of the cast was on September 4th, which was made necessary by hemorrhage from the open wound.

My reason for operating below rather than above the knee was that a former operation (by some one else) had been done, without any result, leaving a thickened bone.

This patient had no after symptoms of any

consequence. She was dismissed from the hospital on December 7th, 1911, at which time she was able to walk without assistance, and to hold herself perfectly erect with the legs in a nearly perfect line, as shown by cut No. 2

CASE III.—THORACIC ANEURISM.

Patient, Mr. E. Z., age 38, seen with Dr. A. P. Mueller on December 8th, 1911.

Personal History: Had been a hard drinker for many years. Denied specific history.

He was first seen by Dr. Mueller in the early spring of 1911, having been ill for some months at that time. He complained of pain in the region of the heart and over the abdomen. Dr. Mueller, at that time, was unable to make out any definite circulatory lesion, but told the patient that there was something radically wrong with his heart. After seeing him a few times the patient got out of his hands, and was operated upon for appendicitis on August 15th by a local surgeon, from which operation he recovered, but his abdominal pains continued as before, except that they were on the opposite side of the abdomen. After leaving the hospital he again called in Dr. Mueller with whom I saw him on December 8th, 1911, the patient never having been able to go to work.

He was greatly emaciated, the abdomen was distended, and he still complained of severe pains throughout the abdomen. Physical examination showed no tenderness in the abdomen and no rigidity of the muscles, which at once suggested to me that the seat of the trouble was not within the cavity. His emaciation was such that the possibility of tuberculous suggested itself, and upon turning him upon his side to make a chest examination, we

noticed a marked change in his respiration, the patient gasping as though he would hardly be able to stand the position. We questioned him and found that this did not occur except when he was lying upon his right side, which suggested interference with the circulatory system. However, we went over the lungs carefully, and while percussing between the ribs at the lower angle of the left scapula, we detected a pulsation. Upon examination of the heart, we decided that he had a thoracic aneurism, and so told his family, although there was absolutely no bony destruction of the wall at that time. An X-ray examination was advised but the patient's financial condition would not permit it. I again saw the patient with Dr. Mueller about the first of February, at which time a pulsating tumor about the size of a child's head, presented upon the back, in the region of the angle of the scapula, fully confirming the diagnosis. The patient died on February 10th. Post-mortem showed a thoracic aneurysm, oval in shape, about 8 inches long and 4 inches in its widest diameter, which had destroyed the greater portion of the discs of the third, fourth, fifth and sixth dorsal vertebrae, and had entirely destroyed the vertebral attachments of four ribs and a portion of the scapula. The rupture in the artery was fully as large as a silver dollar, as shown by the specimen which I herewith present.

The special points of interest in this case are, (1) the diagnosis of thoracic aneurysm before it presented without the bony cavity; (2) the tremendous amount of destruction of bony structure within a few weeks; (3) the rarity of thoracic aneurysm.

DISCUSSION.

Guy P. Grigsby: From the photographs Dr. Spalding has exhibited, I think he is to be congratulated upon the result obtained so far.

I do not understand why incision was made above, as there is no necessity for any incision in these cases as a rule. They can be done subcutaneously in a very satisfactory manner. They are usually done above the condyles and in that way we can get a better correction. A mistake that is usually made in these cases is in putting the limbs up in a straight line, and as soon as the weight of the body is put on them the deformity recurs. Experience has shown that over-correction of the deformity is one of the most important features of the treatment of these cases. I would suggest to Dr. Spalding that, in his case, there is still some deformity in the right leg, and it would probably be a good plan to do a subcutaneous osteotomy on the femur and over-correct it. He has so far gotten such a good result that it would be a pity not to get a perfect one when it can be done so easily. It is wonderful what satisfactory results we get from osteotomy and correction with plaster in these cases.

I would also suggest that this child should wear plaster or other form of support for at least a year or two, so that the bones will develop sufficiently to bear the weight; otherwise the deformity is almost sure to recur.

C. B. Spalding, (Closing): I wish to thank Dr. Grigsby for his discussion. Probably the description I gave of the incision was misleading; I simply made a slight opening in the skin and used the chisel.

I think these bones are thoroughly capable of taking care of themselves. They are as hard as flint now and I do not believe it will be necessary to do anything more.

MEDICAL PROGRESS

DEPARTMENT OF BACTERIOLOGY AND PATHOLOGY.

By EMMET F. HORNE, Louisville.

I.

The Use of Antiformin in Examination of Sputum for the Tubercle Bacillus, W. W. Boardman, Baltimore, *Bull. Johns Hopkins Hospital*, VII., 1911; XXII., No. 245.

An absolute diagnosis of pulmonary tuberculosis can be based upon one, and only one finding—the demonstration of tubercle bacilli in the sputum. Any procedure which will increase the accuracy of sputum examinations should be welcomed. The method here outlined has proven very valuable in the hands of numerous laboratory workers.

Antiformin is a yellowish fluid, the composition of which is similar to Laharraque's solution. It contains about 7.5 per cent. of free sodium hydrate and 5.2 per cent. of bound chlorine. Uhlenhuth and Xylander in 1908 mentioned antiformin as a useful disinfectant. Antiformin has the property of very rapidly dissolving all bacteria, except tubercle bacilli and other acid-resisting bacteria, and the method of isolating tubercle bacilli is founded on this fact.

Boardman describes the technique as employed by Uhlenhuth, Hulse, Meyer, Seeman and others. He says that after trying various procedures, the following was finally adopted as the most satisfactory both as regards method and results.

1. Place the entire 24 hours' sputum in a conical settling glass; if the amount be excessive it is perhaps better to use only 15-20 cc.

2. If the specimen is thick, add an equal volume of distilled water. Less tenacious specimens do not require so much dilution. (Note:—One must be sure that the distilled water harbors no acid-fast organisms.)

3. Add an amount of antiformin equal to

one-fourth the volume of the diluted sputum; in other words, sufficient to make a 20 per cent. solution.

4. Stir thoroughly, thereby breaking up the masses of mucus and greatly hastening complete solution.

5. Allow to stand till solution appears homogeneous. It should now be watery in consistency and pale yellow in color; if necessary, more water or more antiformin should be added and digestion allowed to continue. This will usually require from a few minutes to an hour, but may be allowed to continue for days with no resulting harm to the tubercle bacilli.

6. Add an equal volume of 95 per cent. alcohol. By this procedure the specific gravity is reduced from about 1.030 to below 1.000; thereby not only hastening sedimentation, but making it more complete.

7. After stirring, allow to stand till sedimentation is complete. This will occur in 2-4 hours, but a period of 12-24 hours is recommended. During this sedimentation it may be necessary to gently turn the vessel to dissolve little particles of sediment which may be adhering to the sides of the vessel.

8. Pour off this clear supernatant fluid.

9. Make smear from the sediment on a glass slide, using some of the original sputum to aid in fixing the smear. This is best done by making a smear from the sputum before antiformin is added and afterwards spreading the sediment from the sputum-antiformin mixture on the same slide. Stain and examine in the usual way.

Boardman believes that he is justified in heartily recommending the use of antiformin in the examination of sputum for tubercle bacilli, not only in hospitals and dispensaries but in the laboratory of every private physician.

II.

Beitrag zur Serodiagnostik der malignen Tumoren (Contribution to the Serodiagnosis of Malignant Tumors), Dr. P. v. Monakow, Dresden, Germany, *Muenchn. med. Wchnschr.*, X. 17. 1911-XLIII. No. 42.

As a result of the immense improvement in the diagnosis of infectious diseases through the extension of our serologic knowledge, many experiments have been made in an endeavor to improve the diagnosis of malignant tumors by the application of the same basic principles. Quite a number of attempts have already been made to make possible an early diagnosis through the demonstration of specific antibodies (præcipitins, hæmolysins, complement fixation substances, etc.) in the blood of carcinoma patients.

Monakow mentions the more important

techniques for the serodiagnosis of cancer. He believes that two of the more recent methods offer some degree of success: the meiotagmin reaction of Ascolis and the cell reaction of Freund and Kaminer.

Monakow quotes Ranzi with reference to the meiotagmin reaction: in 234 cases of malignant tumors, the reaction was positive in 89 per cent; while in 233 control cases, normal men or patients afflicted with various diseases, only three reacted positively.

The experience of Monakow with Freund and Kaminer's reaction is as follows: 15 patients with malignant tumors were examined and a positive result obtained in 86 per cent. As control, 52 patients who were known not to have cancer were examined, 25 per cent. showing a positive result, 9.6 per cent. a doubtful result, and 65.4 per cent. a negative result.

Judging from the above figures, the meiotagmin reaction is of greater value than that of Freund and Kaminer. For final judgment as to the relative merits of the two reactions, a greater number of cases must be examined.

To have a test which can be applied with certainty in the diagnosis of obscure cases of cancer will indeed be of incalculable value both to the internist and to the surgeon. Let us be optimistic enough to hope that such a reaction will soon be discovered.

III.

The Blood Picture in Tuberculosis, Margaret R. Lewis, Baltimore; Bull. Johns Hopkins Hospital, XII, 1911-XXII, No 250.

Quite a number of cases of tuberculous were studied and an endeavor made to determine whether the work of Arneth was of practical value clinically. Not only was Arneth's neutrophilic blood picture studied but also the other varieties of leucocytes were noted and counted.

Lewis believes that the neutrophilic blood picture together with the differential blood count is of great value in prognosis in tuberculosis, but not of much value in diagnosis.

A number of conclusions worthy of repetition are given:

1. The number of leucocytes in incipient tuberculosis is between 9,874 and 10,209; while this is slightly higher than most observers have found, it is not markedly different. There is distinct increase in the number of leucocytes with the progress of the disease. Moribund cases show a marked leucocytosis of 26,300.

2. The percentage of neutrophils varies from 64.4 in non-tubercular cases to 78.5 in dying tuberculosis cases. This increase of the neutrophils in the more unfavorable cases is very marked and indicates an unfavorable prognosis.

3. The large lymphocytes according to the statistics show no apparent relationship with the progress of the disease.

4. The small lymphocytes on the other hand did show a very close connection with the course of the disease and this connection might of itself be used as a means of prognosis. In non-tubercular cases and in incipient cases, those cases with good prognosis and those cases whose subsequent history showed improvement gave between 9 and 11 per cent. of small lymphocytes. The more advanced cases show between 4.1 and 6.2 per cent., while the moderately advanced cases and those with doubtful prognosis stand between and have between 7.5 and 7.9 per cent.

5. The eosinophiles decrease with the progress of the disease until in dying cases they are entirely absent.

6. The basophiles give no definite results.

7. The neutrophilic blood picture was represented only by the index. The average index for non-tubercular cases is 54-46, the far advanced cases 75-25 and all stages in between have a corresponding shift to the left in the index. The changes noted for the neutrophilic blood picture were more constant than any other change in the blood and much more so than any of the usual signs and symptoms. In diagnosis the usefulness of the neutrophilic blood picture is not great when taken by itself as other conditions may give a slight shifting to the left, but when considered in connection with the other blood cells and when more than one observation is made, it may be of diagnostic value. In prognosis, however, both at the time of examination and during the course of the disease, the degree of shifting to the left is an exceedingly sensitive indication of the resisting power of the individual and of the progress of the disease.

Neurorecurrences in Syphilis.—At Jadassohn's clinic at Berne thirteen cases of the so-called neurorecurrences of syphilis after treatment with salvarsan have been observed in the last year. Dossekker is sure that the salvarsan has something to do with them, although they are undoubtedly of a syphilitic nature; their frequency since the introduction of salvarsan cannot be explained away on any other basis. The prognosis of these neurorecurrences seems to be favorable, especially if they are promptly detected and treated. The clinics at which a combined mercury and salvarsan technic is applied seem to have had less of these neurorecurrences than others. He urges all to keep a watch for them as neurorecurrences may develop later without the knowledge of the clinician who administered the salvarsan.

EDITORIAL.

SENATE BILL FIFTY-SIX VETOED.

Under Official Announcements, we publish a full text of Governor McCreary's veto message of Senate Bill 56, which was one of the worst measures that had ever been presented to our Legislature. Governor McCreary has again earned the gratitude and confidence of the people he has served so long and so well. This message is really a great State paper on Preventive Medicine and will be read with interest by everyone.

PROCEEDINGS OF THE CHICAGO CONFERENCE ON HEALTH AND EDUCATION.

The following report published in the March number of the *Illinois Medical Journal* will be of interest to our readers:

EIGHTH ANNUAL CONFERENCE OF A. M. A. ON MEDICAL EDUCATION, MEDICAL LEGISLATION, AND PUBLIC HEALTH.—IMPORTANT MEETING.

These conferences grow in interest and importance and the last session held February 26 and 27, at the Congress Hotel, Chicago, was probably more interesting and important than any of the previous sessions. Representatives were present from every state and Porto Rico.

THE FIRST DAY.

Dr. A. D. Bevan presided the first day and gave an opening address. Dr. N. P. Colwell presented his report showing a gradual but healthy improvement in medical college conditions. Unfortunately Chicago, for reasons of which our readers are well aware, shows the least change.

The presence of Mr. Frederic G. Hallett, of London, the executive officer of the conjoint

Examining Boards of the Royal College of Physicians of London, and the Royal College of Surgeons of England, who gave a comprehensive statement of the methods employed in the examinations conducted by these venerable and highly honorable bodies, was one of the very attractive features of the meeting. Mr. Hallett, by means of charts and diagrams, showed that it was entirely feasible to apply the practical tests on patients to all applicants for license to practice medicine and surgery. Several of the states of the Union are already applying these methods, and there is no good reason why all should not. Dr. Bevan stated that this could be readily done in Chicago.

Another address which was highly commended was that given by Prof. Reuben Peterson of Ann Arbor, on the Relation of Medical School to the Intern or Hospital Year. The extensive and interesting discussion of this paper by Drs. Murphy, Vaughan, Means, Lambert, Jackson, LeFevre and Dyer representing all sections of the country, was notable in that each and every one commended the magnificent work done and contemplated by the Michigan school, and the necessity of giving each graduate comprehensive and systematic course in hospitals. The hospitals must be brought up to a standard, and made to be something more than boarding houses for the sick. A resolution was adopted requesting the Council to make a systematic inspection of all hospitals with a view to their availability for intern instruction.

The last topic, a symposium on Medical Education in the State, was notable among other things for the frank acknowledgement on the part of one of the speakers, that the Carnegie Report on Medical Schools issued in 1910 was correct, and one of the most beneficial criticisms on the existing conditions that could have been made. He took occasion to emphasize the language of that report which declar-

ed Chicago the "rotten spot" of the medical education world. The reiteration of this statement was greeted with an applause which spoke louder than words.

THE SECOND DAY—MEDICAL LEGISLATION AND PUBLIC HEALTH.

Dr. Henry B. Favill, of Chicago, presided and uttered an address which was quite remarkable, and led up to the most dramatic climax it has ever been our privilege to witness. Dr. Favill's remarks were to the effect that the activities of the profession in political matters had brought about considerable criticism from a portion of the public. We had been accused among other things of being "a professional trust"; or using "trade union methods"; of "abandoning our high ideals and stooping to political methods," etc., etc. Because of these disagreeable statements Dr. Favill thought it the part of wisdom to at once abandon our efforts along political lines and depend altogether on our efforts to educate the people. He further made the remarkable manifesto that this wise conclusion reached after long and exhaustive study of the subject, being the personal opinion of the chairman, could not be discussed. All present were amazed at the temerity of the chairman, and wondered what would be the effect of his pretention to infallibility in a matter so near to the heart of the profession and so important just at this time.

THE DRAMATIC CLIMAX.

Scarcely had the chairman taken his seat ready to call for the next order of business when Dr. J. N. McCormack of Kentucky sprang to his feet, and in eloquent language called attention to the stand taken by the parent organization at the Los Angeles meeting. The representatives of the organized profession duly elected and clothed with plenary power had pledged the organization at its annual meeting to a continuation of the contest which it had commenced, and instructed its committees and its journal to use their utmost endeavors to procure the passage of the Owen bill. If it should go out to the public that this conference, after all that had been said and done, had to-day taken a different stand, and should by its silence give consent to the doctrinaire sentiments of the chairman, a blow would be struck at the good faith of the profession from which it would never recover. Mr. Owen, who had taken his life and his political fortune in his hands in advocating our cause, would go down to a disgraceful defeat, and the blood of this sacrifice would be on our hands. McCormack said that he had just come from a contest in Kentucky, which showed the extremities to which the enemies of the profession would go to bring about his overthrow. Thanks to the united stand which the

profession and the people of this state had taken, the enemy had been beaten horse, foot and dragoons. The effect of McCormack's eloquence was magical, applause punctuated his statements, and when he concluded the acclaim continued for several minutes. We have never seen anything like it on the floor of a medical meeting.

The supra climax came at 4:30 p. m., when a resolution pledging the active support of the profession to the Owen bill was passed by a unanimous vote of the members present. As our readers well know, this bill proposes the consolidation of the three existing bureaus into one central national board: (1) the Public Health and Marine-Hospital Service, now under the Treasury Department, (2) Vital Statistics, now in the Census Department, (3) Bureau of Chemistry, now in the Agricultural Department. Another resolution adopted calls for the formation of a national council on public health under auspices of the American Medical Association. The aim is to bring together annually or oftener all federal, state and municipal health officers for discussion of health and legislative subjects. Through such an organization, it is contended, health officials will be able to standardize and systematize their work and wage a united campaign for proper health legislation in nation, state and city. Congress was asked for financial support for the international congress of hygiene and demography at Washington in September.

The Council on Health and Public Instruction was asked to draft a model medical practice act as soon as possible.

A committee to investigate the status of vaccination and small-pox statistics and to prepare a model bill on vaccination for introduction in legislatures of all states will be formed.

A committee to consider changes and modifications of the present model law on registration of vital statistics will be formed.

Establishment of a pure food and drug board of examiners in every state was advocated by E. F. Ladd, state commissioner of foods and drugs of North Dakota, in an address.

There should be a board in every state to pass on patent or proprietary products coming on the market, he said. "When a product was found to be a fake no license for its sale should be granted; or if the advertising or descriptive matter were false or misleading—either that accompanying the product or as published through the press—then the license for the sale of this product should be revoked." Commissioner Ladd urged an agitation for the enactment of a general merchandise marks act, making it an offense for any

manufacturer to sell any manufactured product under a false label.

Dr. J. W. Pettit, superintendent of the Ottawa Tent Colony, outlined a program against tuberculosis.

AN APPRECIATED EDITORIAL.

The following editorial from the *Log Cabin*, of Cythiana, of March 1st, will be read with interest by the profession of the State. It is a beautiful tribute to the effectiveness of the medical profession of Harrison County and a fitting rebuke to the so-called League of Medical Freedom, which is really a League of misguided cranks for whom idea funds are supplied by the Patent Medicine, Adulterated Food and other corrupt interests:

"We are in receipt of a most remarkable circular letter from Louisville, signed by one Ben F. Alford, making a ridiculous attack upon the State Board of Health and criticising the election of Dr. South as president of the board.

"The letter tells of the purposes of the 'League for Medical Freedom' which is fighting against compulsory vaccination; the destroying of dairy cattle, (Mr. Alford fails to say diseased dairy cattle); the destroying of food supplies (Mr. Alford fails to say adulterated food supplies); the requiring of physicians to secure a state certificate before practicing medicine in Kentucky. As the *Log Cabin* heartily indorses each of the above mentioned things which the State Board is endeavoring to enforce, we respectfully decline to give any assistance to the alleged 'League of Medical Freedom.' In our opinion, any physician opposed to vaccination is fifty years behind the times. In our opinion every physician who presumes to treat diseases should be able to meet the requirements of the State Board of Health. There are so many medical colleges in the country that a diploma has a very indefinite meaning. Even lawyers and school teachers, no matter what diplomas they hold, must undergo an examination to determine their qualifications before they can practice or teach. And it is very much more important that the people have some slight protection against the medical incompetents and the fakirs. The physician who is qualified will not object to the reasonable requirements of the State Board of Health, and those who can not meet those requirements are a menace and ought not to be allowed to attempt to practice medicine. In our opinion there is no class of men who do more unselfish labor, without reward, than the medical profession. Right here in Cythiana the present winter we saw the physicians volunteering to take their turns in going to the city schools, free of charge, and examining the children's throats so as to detect the first

symptoms of diphtheria. But for this medical examination the schools would have had to close or a widespread epidemic of diphtheria would have followed. Many people will doubtless be misled by the insinuating and indefinite harangues of the 'League for Medical Freedom' but we are very sure that every legislator and every citizen is doing his state a splendid service when he upholds the State Board in every effort to secure pure foods, pure milk, healthy cattle, and to keep the quacks and the incompetents out of the medical profession."

YOUR SUBSCRIPTION EXPIRES.

Your subscription to the JOURNAL expires with this issue and this is the last number you will receive unless you have handed in your dues to your county secretary, who is our representative in each county.

It is with pardonable pride that we announce that we have the largest number of subscribers on our roll that we have ever had.

DR. D. C. BOWEN.

In the death of Dr. D. C. Bowen which occurred at his home in Elizabethtown, on March 15th inst., from tuberculosis, the State of Kentucky loses one of its foremost citizens. Dr. Bowen was not only one of the best practicing physicians in Kentucky but he was a broad-minded, indefatigable, medical statesman, was Councilor and Vice President of the Kentucky State Medical Association. He served it so well that he was unanimously elected a life-member several years ago, an honor which has been conferred upon no other man. Dr. Bowen's memory will be enshrined in the hearts of the medical profession of Kentucky forever.

RETROSPECTION.

The year 1912 has thrown off its swaddling clothes and all it has to write of medical history is, as yet, to be surmised, but it is to be firmly hoped that it, when it closes, will be counted among the years past when great things have been accomplished. I say this, when we review the history of the year 1911, it was not an epoch maker in medical history but in preventive medicine. It is now occupying the minds and keeping thousands of busy hands at work, has enough brilliant discoveries of recent years to place it in the Hall of Fame. It has been only a decade since the mosquito borne infection of the yellow fever was given to the world and to-day the great scourges of yellow fever that claim its thousand victims as told, is now but a memory. The history of Panama is another page in the history of preventive medicine of which we workers in this great field are proud to point

to and say to the world that we Americans did it. When you stop to consider what Colonel Gorgas has accomplished, not only in Panama but Cuba, one would almost stand aghast and marvel and exclaim that indeed there are new things under the sun. He stands there firmly with the sanitary situation of that territory absolutely in hand and the morbidity is lower than some of our cities and the death rate excepting occupational deaths is equally as low. Cleanliness, much living in the open, the God-sent porch, open air, good water, plain well-cooked food and an unceasing, annihilating fight against mosquitoes, flies, fleas and other insects, tell the story of his work and why it has been worth the while. Another achievement of former years that we are busy with is the hookworm crusade. To all it is wonderful and is worth the time and labor that is being devoted to it, from a diagnostic standpoint as well as a crusade to eradicate. And then again, tuberculosis is claiming the attention of both the profession and the laity more at this time than any other time in the history of medical literature. The daily press is carrying on a propaganda against this great white plague. Normal schools all over the land are disseminating knowledge of prophylaxis to the teachers that are going out and educating the young men and women of the next generation.

Municipalities, all over this great land, are spending more money, employing more trained men, taking the great machinery of preventive medicine out of politics, executing rules and regulations, bettering the sanitary conditions of their states, of their transit cars, of their great department stores, they are passing rigid and stringent ordinances covering the building equipment and care of tenement houses. I say these and many other things are occupying the minds and busy hands of the health worker of this land.

It is with pride that Kentucky health workers can show a record of work done and results accomplished in far greater ratio than the money appropriated by the different fiscal bodies. The Kentucky health officers are in the front rank and are doing things.

PHYSICIANS' MISTAKES; LACK OF CONFIDENCE.

We are living in an age of doubt. This is the day of the skeptic's choice. A world-wide mental and moral unrest indicates how shaken are the foundations of belief. We hold opinion but loosely and subject to ready revision. The world is sure of but one thing today and that one thing is, that it is not sure of anything. There are no established beliefs, no settled convictions anywhere in the life of the present. Even the ancient polities of China, the conservatism of the Church and the ultra-

conservatism of the Law are in the turmoil of transition. If any deny that this is an age of rapid progress he must admit that it is a time that holds itself ready for progress.

In such an age it is not strange that medicine should be permeated with more than wholesome doubt, for medicine, never satisfied with the past nor content with the present, has ever had her eyes to the front. Alert for improvement she has always questioned her best results in the interest of better.

It is not strange that medical men, somewhat shaken in old beliefs and not always grasping the new, should have fallen into doubt overmuch. There is a healthy skepticism which, too highly cultivated, exhausts the mental soil in which belief should grow. We question our science and mistrust our art. We believe too feebly in our work, in ourselves and in each other. We distrust our diagnosis, discount our prognosis and suspect our treatment.

The doctor is not excusable even in his own eyes for leaving himself in unnecessary doubt. Faithful study of his science, thoughtful practice of his art and painstaking examination of his patients will solve most of his doubts. Such as remain unsolved even with the aid of consultation he may in good conscience leave to the future advances of medicine.

Nor is the physician excusable for feigning his doubts in explaining the ease to the patient or his family. They can give no material assistance in solving them and usually have doubts and anxieties enough of their own. It is not suggested that deception be practiced. Honesty and fairness toward the patient and to himself often unite in requiring that the existence of doubts be acknowledged by the physician. Doubt emphasizes itself in the conscientious physician's mind and looms large in his thinking. He must not emphasize it to the patient but should put the stress upon the positive side, explaining his beliefs and hopes rather than his doubts and fears. The physician should be a man of faith in his science and confidence in his art, of belief in himself and assured certainty in his work. Without faith he can not inspire hope and unbelieving he can not rejoice in his work and joyless work of drudgery. We may appropriately repeat for ourselves and for our patients the invocation of Saint Paul, "Now the God of hope fill you with all joy and peace in believing." W. W. A.

AGAR IN CONSTIPATION.

Those physicians who have learned the value of ripe, red apples are invited to give attention to another, similarly efficient and safe remedy for the treatment of habitual constipation. As in the case of apples the remedy is not of a proprietary nature and hence no kind-hearted manufacturer will supply them with glowing accounts of its virtues, instead they must learn its properties in other ways. The remedy is worth the study, however, and with it, as in the case of apples, they may win the confidence and gratitude of their patients.

The remedy is agar agar, or simply called agar, and it is described in New and Nonofficial Remedies. It is not yet kept in every drug store but any druggist, if requested, will obtain it from his wholesale house. It comes in pieces like gelatin, in shreds or in a more or less coarse powder. Its method of administration is fully described in the "Truth about Medicine Department" of this issue. Agar acts mechanically by producing a bulky stool and produces no after effects as do ordinary cathartics.

If physicians will familiarize themselves with this drug, they will forestall the exploitation of many a proprietary preparation consisting of agar with a little dab of this or that for which most marvelous claims are made and an exorbitant price is charged.

Take our advice, get from your druggist a supply of agar, study its effects, find a pleasant method of giving it, and earn the gratitude of your patient by supplying them with a safe and efficient cathartic.

RADIUM EMANATION AND GOUT.

Recent investigations indicate that the monosodium urate of the blood exists in two forms differing in stability. In the blood of gouty persons containing an excess of uric acid, it is the more insoluble form which is responsible for the deposits in the tissues. It has been discovered that radium emanation is capable of splitting off nitrogen from the more stable form, making it more soluble and even decomposing it with formation of carbon dioxide and ammonia. Further studies showed that the metabolism of human beings on a purin-free diet, could be markedly affected by inhalations of radium emanation. Gouty patients exposed to the radium emanation showed an increased excretion of oxogenous purins, and the uric acid disappeared from the blood. It is also asserted that tophi actually became smaller or even vanished under the influence of the emanation.

While the investigators no doubt appreciate that the actual value of radium in the treatment of gout is still to be determined we

may forthwith expect to see advertisements for radium gout cures of all kinds and descriptions.—(*Jour. A. M. A.*, Feb. 24, 1912, p 560).

GELSEMIUM.

In these days of brilliant surgery, the various uses of bacterins, sera, the palatable elixirs and combinations of drugs put out by manufacturing druggists and chemists, we are prone to get away from individual drug action and study. It behooves us, therefore, to consider individual drug therapy, and for this reason I am constrained to briefly write of gelsemium, one of the old time therapeutic agents.

Gelsemium has been a favorite remedy with the writer for a long period of years and many opportunities have been presented for a thorough "trying out" of this valuable therapeutic agent.

I might say at the outset that I prefer the fluid extract, it being a more stable and reliable form, beginning usually with small doses and increasing until the full physiological effect is produced.

Internally it is a powerful motor depressant and sedative. "In moderate doses, but sufficient to produce decided physiological effects gelsemium causes a feeling of languor and mental calm, slowing of the action of the heart, drooping of the eyelids, dilatation of the pupil and some feebleness of muscular movement. In larger doses the physiological effects are vertigo, double vision, amblyopia, paralysis of the levator palpebrae so that the upper lid cannot be raised, dilated pupils, labored respirations in consequence of a paretic state of the respiratory muscles, slow and feeble action of the heart, great muscular weakness, and sensibility to pain and touch much reduced."—Bartholow.

Gelsemium is especially valuable in excessive nervous irritability, as in neuralgia, ovariagia, tic doloureux, myalgia, lumbago, intercostal neuralgia and sciatica.

In spasmodic coughs, especially whooping cough, it often affords relief. In cerebral congestion and irritation, combined with the bromides it is of value. It is of marked advantage in ovarian irritation, painful menstruation and pelvic disorders of a like character and is to be preferred to opium because it does not produce a "habit."

It is especially valuable in acute coryza and influenza and in some cases of spasmodic asthma great relief is afforded by gelsemium.

Lumbago, which is really in many cases, a neuritis, has yielded time and again in my practice to large and increasing doses of gelsemium.

I very recently had an opportunity to prove its value in a stubborn case of sciatica which

had resisted various remedies and measures.

It is advisable always when giving gelsemium to keep the patient in a quiet, prone position and its efficacy is increased by so doing.

It has a decided sedative influence in the acute neuralgias and is permanent in its effects.

It does not irritate the stomach nor lower blood pressure, though it slows the heart and lowers the body temperature thereby proving useful often in acute inflammation of the lungs and pleura.

SCIENTIFIC EDITORIALS.

McFADDEN'S PHYSICAL CULTURE PROPAGANDA.

Bernarr McFadden, physical culturist and athlete, "struck" Louisville last week, enabling the writer of this editorial to form an opinion concerning one who has played quite a conspicuous part along physical culture lines. McFadden is a man of many parts, or supposed to be; physical culturist, editor, lecturer, physical culture physician, and a strenuous opponent to medicine and medical men. Incidental to his lecture, he tries to secure subscriptions to his magazine "*Physical Culture*," and his five volume "*Encyclopedia of Physical Culture*." He has a most excellent optic for the business and monetary side of the work.

I should say McFadden was about five feet, ten inches in height; well built, rather broad of shoulder, deep of chest, and strong of arm and limb. He preaches the gospel of spiritual and physical vitality, but I have not seen a face in a long time that so typically represents the lack of all that he preaches: in fact, his facial expression is dull and heavy. In making his entrances and exits, there are indeed few upon the lecture platform who walk as badly, and whose movements are as ungainly as this preacher of a propaganda of a muscular grace and activity. His voice is deep and has good carrying qualities, but possesses a huskiness of tone that robs it of considerable of its power. His sentences are often incomplete; the ideas are rarely carried to a logical conclusion, and his intonation and delivery are, to put it mildly, very poor. He uses a great many gestures, but they are poorly made, are untimely and seem inexpressive and with no purposeful intent. One would think, after his long years of experience upon the platform, he would have mastered this art of the lecturer and declaimer. When we compare his movements to the finished acting of even the average actor, or if we compare him, for one moment to such men as Wm. Jennings

Bryan, W. C. P. Breckinridge, or other well known platform orators, he suffers badly.

McFadden gives one the impression of being rather a restless, nervous, individual, who passes from one side to the other of the stage, lacking repose and power. In fact, while he possesses *strength*, he seems to lack that *powerful nerve vigor*, that can be quiet or active, as the case may demand. To my mind, he is absolutely devoid of that intangible tangibility, magnetism. In fact, he impressed me as being mentally slow, with the slowness of the strong man but in thought and action. If one takes the trouble to compare him with that paragon of physical development, James J. Corbett, while they are similar in many respects, the difference is marked. Corbett is quick and restless, but he is bright of eye, clear of voice, full of magnetism, and when he does move, his movements resemble the agility, strength and subtlety of the leopard and the tiger. Corbett is full of a wonderful magnetism, and to my mind, he had in his time, the handsomest physical body that my eye has ever rested upon; even in his gladiatorial contests, one could never forget, nor lose the impression that he was "Gentleman Jim."

Physically, McFadden is to me, a unique marvel. I am constrained to believe that every muscle in the man's body is most wonderfully developed. His marvelous nerve control of single muscles and muscle groups, I have never seen on another human being, and I have seen many strong men.

I think he is better developed than Sandow, but he is certainly not as strong, although he did some card tearing tricks that were most excellent "stunts". In his posing, he could do very much better, if he would be a trifle more statuesque. The development of the abdominal and back muscles, baffles description: they were perfect. No one can say that McFadden is not a wonderful man when it comes to muscular development.

His *medical pathology* is a most curious one. Tersely put, it is as follows: If one has a disease, it is a necessary thing, and an advantage, as you get that much (whatever it is) out of your system, as the disease comes from waste. In other words, if you have a cold, you ought to, and should have it, in order to get that much out of your system. And this applies rigidly through his lecture to infections, the cause, origin, course, duration, pathology, pathological anatomy and therapy of which are well known, and fairly fixed. His whole pathology is misleading, farcical, puerile. The origins of disease are errors of diet, impure air, and lack of exercise. Some of his illustrations are in themselves a *felo de se*. For instance, he says that in the New York hospital, they treat diphtheria by regulating the

diet and exposing the patient to fresh air. He failed incidentally to mention that the hospital uses *antitoxin*, his much *hated drugs*, and that the children are superintended by that dangerous class, *medical men*. He says he has had pneumonia five times, has diagnosed it himself without medical aid, cured it by his own measures, that is, by diet, exercise, etc. Argumentatively, if Mr. McFadden has had pneumonia five times, he certainly has not the vitality of the strong man that he represents himself to be, especially, in view of the fact that some of us weaklings, among whom may be classed the writer, have never had pneumonia at all. The whole thing reminds me of the story of the lawyer, who conducted his own case, and realized, alas too late, that he had had a fool for a client. "Get it". McFadden's propaganda is fraught with danger, is false, and apt to do great injury to many people, who might be led away, through ignorance, and at the same time, it is little short of an insult to modern intelligence to refer to doctors as he does, and to advise against their employment in the management and treatment of disease.

There is no question in this world, but what proper diet of good food, freed from the poisons of dishonest manufacturers (*ala Wiley*), properly prepared, in rational quantities, thoroughly masticated, is a good idea to advance, but the question of what diet, both for health and disease is a question for the physician, who must adapt himself to the particular individual. He, speaks of *fresh air*. Says he "dotes" on drafts and that these constitute one of the greatest blessings of fresh air. No thoughtful man that can reason, but will know that drafts should be avoided, that they are not necessary and in no sense of the word do they constitute "fresh air." No physician prescribing "*pure air*," which is much to be preferred to "*fresh air*," would do otherwise than caution his patient against exposing himself in the manner suggested by McFadden. I am a profound believer in exercise; I believe it one of the best methods of preserving health, but the development of muscle *ala McFadden* is totally unsuited for the many business and professional men, who have a living to make in these most hard and strenuous times. Business and profession demand a vast expenditure of nerve force, and all the exercise the average man needs is just enough to keep his muscle loose and firm, his secretions active, and his circulation good. In my opinion, nothing beats walking, deep breathing, or the digging and working in the flower bed or garden.

In my opinion, Mr. McFadden omitted one of the greatest preventative of disease, and the most powerful reconstructive in health and disease known to medical science, namely

tonic hydrotherapy. By tonic hydrotherapy, I mean the judicious, carefully prescribed use of cold water, adapted to the particular case in hand.

In conclusion, it may be said that the question of health getting lies exclusively within the domain of the physician's work, and not in that of a *maitre d'instruction* of physical culture. To put it more plainly, if physical culture is needed, the instructor should be subservient to the doctor, the two working hand in hand. It cannot be said that because a person adapts physical culture to the means in hand, that he does not require other therapeutics, possibly including surgery, simply because he uses one rational means of health getting, and health preservation. In his work, Mr. McFadden assumes more than lies in his legitimate field of activity, and what I have said herein in praise or in criticism is said without the slightest disrespect, but with the firm belief that Mr. McFadden would serve a far more useful and better purpose, were he to link his destinies with the scientific and legitimate practice of medicine.

CURRAN POPE.

FORCEPS IN PERSISTENT OCCIPITO-POSTERIOR CASES.

When the occiput points to either the right or left sacro-iliac synchondrosis and remains persistently posterior, or even shows a tendency to rotate into the hollow of the sacrum, then delivery should be effected by the double forceps application of Scanzoni.

In this operation, complete rotation of the head must occur in the blades of the forceps, from the sacro-iliac synchondrosis to the symphysis pubes and it can be readily appreciated, that if the diagnosis of position is faulty and this rotation is attempted in the wrong direction, that delivery will of course be retarded and serious injury inflicted upon the child. With a proper diagnosis and skillful performance of the operation, it forms one of the most beautiful of obstetrical demonstrations, in that it quickly and safely terminates a condition, that has been causing the patient long hours of suffering and anxiety.

In occipito posterior cases, the sagittal suture is in the oblique diameter of the pelvis, with the small fontanelle pointing towards the sacro-iliac synchondrosis. The diagnosis is evident from finding the large anterior lozenge shaped fontanelle forward at one of the acetabula, the small fontanelle generally being far back and up, beyond reach. The location of the fetal heart sounds in the flank, with the delay in labor, are additional aids in diagnosis. Under all circumstances, however, the diagnosis should be definitely confirmed by palpating the ear when the hand is intro-

duced under full anesthesia for application of the forceps.

The R. O. P. position is the most frequent and the operation in such a presentation will accordingly be described. The cephalic application is the only proper one, the blades grasping the sides of the head by placing the left near the left sacro-iliac synchondrosis and the right, near the right acetabulum, the instruments extending well up, in order to get a firm grasp upon the head. When locked, the handles will point downward and toward the left thigh of the mother. The operator must now remember the normal mechanism of occipito posterior position and must have an accurate picture of the existing condition that he is about to correct, in his mind. It is his object, to bring about descent and then to aid normal rotation of the occiput forward. As is well known, the delay in forward rotation, is due to the fact, that the occiput has not descended far enough.

Traction on the handles is at first made downwards, pressing against the perineum. After a few such efforts, if properly directed, it will generally be found that during the next traction, if a slight rotary motion forward is given to the instruments towards the mother's right, that no resistance will be felt and if that is the case, then the obstetrician continues the rotation during that traction, until he has brought the occiput under the symphysis pubis. The handles of his instruments at the end of this manoeuvre, will be in the median line, pointing forwards and the entire forceps will have reversed, the lock pointing towards the floor.

The sagittal suture is now in the anterior-posterior diameter of the outlet, with the occiput under the symphysis pubis. The forceps are unlocked and removed and then re-applied to the sides of the child's head in its new position. This, the final step in the procedure then becomes simply a forceps delivery at the inferior strait, with the occiput pointing forwards and delivery is conducted accordingly.

EDWARD SPEIDEL.

OSTEOMYELITIS.

Let us understand that this term is applicable to any form of bone infection that involves the medullary substance either primary or secondary. We propose to limit the present study to a view from the standpoint of the essential causes. Any of the pathogenic organisms are capable of producing inflammatory processes in bone as they are in soft tissue and the pathology is quite analogous. The clinical course of bone infection is modified by the variety, virulency and volume of the infecting agent. The clinical history of tubercular infection is characterized by chron-

icity. Syphilitic infection is characterized also by chronicity and formation of gumma. The infection of the more strictly pus producing germs such as the strepto and staphylococci and the colon bacillus are characterized by acuteness. Now the site of infection is also relatively dependent upon the variety of the infecting agent. Thus tubercular infection is most frequently found in the metaphysis in adults, and the spongy portion of the diaphysis in children. Syphilitic infection shows a strong predilection for the osteogenetic layer of the periosteum overlying the shaft of long bones and surface of flat and irregular bones. The pyogenic organisms such as mentioned above show a tendency to affect primarily the interior of the medullary canal. The symptoms of tubercular bone infections have in the past misled many but they are not to be considered as misleading. The greatest misfortune in connection with infections of bone, especially in the neighborhood of joints is the fact that they are treated for long periods under the diagnosis of rheumatism. I have seen a case of tubercular hip joint disease that had been treated for 12 months, for rheumatism.

Pain is the first announcement of trouble. It is most pronounced after exercise and children thus afflicted will show a marked tendency to avoid indulgence in the usual diversions of childhood. Later swelling and tenderness make their appearance. In the case of tubercular infection there is but little redness of the surface over the affected regions. Slight fever is almost always present. There are frequently tubercular foci in other portions of the body. These cases should receive treatment of appropriate kind before extensive destruction of tissue takes place. The technique of the operation would depend upon the site of the infection. In case it is the diaphysis the bone should be freely exposed and a subperiosteal division of the bone should be made through perfectly healthy structure with a Gigli saw and the affected section of bone peeled out from the periosteum. The two layers of the periosteum should then be sutured together making a rather thick ribbon which under the least favorable circumstances can reproduce the bone. In the removal of the section of bone in the manner described it can be separated from the epiphysis below thus insuring the future growth in long axis of the remaining bone. As it is almost invariably in children that the tubercular infection is proximal to the epiphyseal line this becomes a most fortunate circumstance. It is well to remember that in children tubercular investment of bone always occur in the diaphysis line or upon the synovia. It is in primary infections of the synovia that injections of an antiseptic fluid into the joint accomplish

the greatest good. I do not believe that it is worth while where the bone is primarily affected. There are two noted exceptions to the rule of complete excision of infected bone and these are in bones of the carpus and tarsus. When they become infected total ablation of the bone affected is demanded. Excision of the hip is not considered feasible in the majority of cases because of the great difficulty of reaching the affected area.

In adults tubercular infections of joints often occur as miliary tubercles upon the synovial membrane. And later appear in the metaphysis of the one or other or both of the bones entering into the formation of the joint. It is in the event of primary synovial infection that antiseptic fluids injected into the joint cavity early in the course of the disease often affect a cure. But, I repeat, I do not believe much if any good is accomplished by this method when the bone tissue is attacked. Naturally temporary immobilization is a constant aid to treatment of any infected joint. When the bone structure is involved excision of the diseased bone is imperative. This of course results in ankylosis if both bones entering into the joint are thus excised. Particularly is it noticed in connection with knee-joints. But I have excised the head of the humerus and secured an extended range of mobility and a thoroughly usable arm also I have excised the tibia in its lower extremity without interfering with the mobility of the ankle joint and maintaining 75 per cent of its utility.

In the forms of infection characterized by acuteness the original focus occurs in the medullary substance of the pipe bones. This condition is characterized by pain of excruciating character, occurs most frequently in children from 6 to 12 years of age. Although younger and older persons are not immune. The process is a suppurative one and it rapidly converts the bone marrow into pus. Necrosis of the bone does not begin to occur until the pus which is confined in the medullary canal begins to burrow toward the surface and the endosteum is destroyed. At this stage the confined pus finds the place of least resistance in its bony casement and bores through until it reaches the periosteum when instead of boring straight through the periosteum to the muscular planes above, it finds the direction of least resistance between the bone and periosteum. It then travels along the shaft lifting up and dissecting away the periosteum in its path until yielding to the combined influences of tension and sepsis the periosteum break at some point. The pus then pours out into the muscular structure of the limb and appeared upon the surface. Tracing this pathological history through its several stages it is obvious that each stage de-

mands certain special forms of treatment. If the diagnosis can be made (and it surely ought to be) before destruction of endosteum has ensued the problem of treatment is the simple one of drainage.

This can be accomplished by boring into the medullary canal at one or two points along the shaft of the bone. If treatment is not begun before the escape of pus through the bone and beneath the periosteum then treatment consists in an incision sufficiently long to drain the sub-periosteal space, and enlargement of the perforation in the bone to expedite drainage of the medullary canal. In the cases that we see in which sinus is established the pathological conditions of the bone, periosteum and endosteum have become complicated. The resistance of periosteum is so great that it will delay perforation until the pus confined beneath it has brought about, by septic influence, necrosis of extensive areas of bone forming sequestra. A sequestra may consist of the entire shaft of a long bone. The periosteum under the stress of septic irritant thickens upon its fibrous layer and proliferates bone cells upon its osteogenetic layer until it produces a mass of new bone which is much larger than the original. The fatal weakness of bone thus produced is its lack of weight bearing power and the fact that it envelops a mass of necrosed bone. It is poorly nourished, being analogous to exuberant granulations in soft tissue. Treatment in this stage is complex. It should consist in total excision of both involucrum and sequestrum. An ample incision is made over the long axis of the bone down to the periosteum. The periosteum is split and peeled back on either side and sub-periosteal division is performed at each end of the affected bone. Great care should be taken to make the division through the healthy bone if this is not possible the bone should be disarticulated and the entire structure removed. The two layers of the periosteum should then be sutured with catgut and the limb maintained in a position to prevent deformity. The periosteum will reproduce under these conditions, new and healthy bone with ample weight bearing function. I have now in my possession specimens of entire tibia which were removed and have since been reproduced as shown by X-ray photographs which I also have. Both patients have useful limbs. I have entirely excluded the curette and the gouge from my technique of bone lesions.

G. A. HENDON.

OFFICIAL ANNOUNCEMENTS

GOVERNOR M'CREARY'S VETO MESSAGE.

In the following message the Governor disapproves the so-called tuberculin bill:

"Senate bill No. 56 is entitled 'An act to provide for the inspection of bulls, cows and calves, held and owned in this State, for the testing of same, for the destruction of same having tuberculosis, and prescribing a penalty for using reacting animals for dairy purposes.'

"This is one of the most important bills enacted by the Legislature which recently adjourned, and I have given it careful and thorough examination.

"One of the greatest problems confronting the people is the increasing prevalence of tuberculosis among cattle and human beings.

"A careful estimate made by the writer for the international congress on tuberculosis for 1908 shows that tuberculosis of animals exacts a total of over \$23,000,000 annually. Of even greater moment than this tremendous economic loss is the sacrifice of human life and the impairment of human health from tuberculosis, almost universally regarded by scientific educators as due to a considerable degree from tuberculosis in animals from which milk and other foods are derived.

THE TOLL IN KENTUCKY.

"Vital statistics show that 5,181 people died in Kentucky from tuberculosis last year, and it is estimated that there are now 15,000 cases yet living in Kentucky who have this disease, and tuberculosis is usually contracted in the intestines of both adults and children through the use of infected milk.

"No one who is informed on this subject can fail to realize that every proper effort should be made to check the spread of tuberculosis, and no appeal should be heeded more promptly than that now being made in behalf of the health and life of human beings, and in favor of the extinguishment, as rapidly as possible, of this terrible disease.

"It is a well-established fact that all the germ-producing diseases come from a germ, which, if it be planted in the body of human beings, will likely take root and grow, and multiply to an extent that will poison the individual and ultimately destroy life. A germ of tuberculosis from a cow, if it gets in the milk and then into the stomach of an infant or adult will grow and multiply, and produce the deadly disease known as tuberculosis.

In July, 1909, the State Board of Health issued a proclamation setting forth certain

regulations. One of the regulations was as follows:

"'No milk shall be permitted to be sold or disposed of in the State of Kentucky unless the cows producing the same shall have been tested and show reaction to tuberculin.'

"This regulation was earnestly opposed but the Court of Appeals of Kentucky (the whole court sitting) sustaining the law unanimously, and in one sentence of the decision declared:

"'Better kill the cows than kill the children.'

LAW ON STATUTE BOOKS.

"We have had in Kentucky for the last eighteen years a law on the subject of contagious or infectious diseases affecting cattle, which can be found in Chapter 5, Article 2, Sections 48 to 63, inclusive, which has given great relief, and has operated to the satisfaction of experts and those well-informed on the subject of tuberculosis and cattle diseases, which, according to the statistics of a number of our best surgeons, physicians and veterinarians, is preventing or stamping out tuberculosis and other cattle diseases.

"Senate bill No. 56, now under consideration, changes this system and the treatment which has been successful for so many years, and leaves the matter of inspecting cattle to the discretion of the Fiscal Court of each county, and the application of the tuberculin test is made a question of arbitration between a veterinarian appointed by the court and one representing the owner of the cattle; a third veterinarian to be employed where there is a failure to agree, who must be a resident of the neighborhood. Between the discretion of the court and the arbitration of veterinarians much time would elapse, and the possibility of no satisfactory action would be great.

"Under the law, which has been in force for eighteen years, a board thoroughly competent and experienced, with authority to obtain the services of veterinarians in the employ of the United States, and otherwise co-operate with the proper departments of the Federal Government and persons appointed by the Governor to act with the board, and with authority, with the approval of the Governor, to use not exceeding \$3,000 per annum for the purpose of paying for such cattle as may be condemned and slaughtered, have been doing effective work, so that tuberculosis has entirely disappeared in various sections of the State, and has been greatly improved in others.

"So much interest, so much feeling, and so much excitement have been aroused, that I, as Governor, take hold of this subject with some anxiety; but I feel that I should do my duty in the interest of the people, and the health and life of human beings should not

only be considered first, but they should be protected first at all hazards.

PROVISIONS OF THE BILL.

"Senate bill No. 56 provides as follows:

"Section 1—The Fiscal Court of each county in this State, upon the recommendation of the County Board of Health in such county, or upon the recommendation of the General Council of any city or town, may select a duly qualified veterinarian in such county, whose duty it shall be to examine and inspect, once in each year, all bulls, cows and calves held and owned in such county, at the expense of such county, for the purpose of detecting tuberculosis among same, and to apply the tuberculin test to such cattle owned and held in such county in the State of Kentucky, at the expense of such county, provided such veterinarian, selected as aforesaid, shall discover evidence of the existence of tuberculosis in such cattle in said county, proposed to be tested. If the owner of such cattle, proposed to be tested, should object to such test being applied, upon the ground that such cattle do not show physical evidences of tuberculosis, then said owner shall have the right, at his own expense, to designate a veterinarian to examine such cattle; and if the said veterinarian so selected agrees with the said veterinarian representing the county, that such cattle show physical evidences of tuberculosis, then said cattle shall be tested with the tuberculin test; but in the event said veterinarian does not agree with the veterinarian selected by the Fiscal Court, that there are physical evidences of such disease, then said two veterinarians shall thereupon select a third veterinary, who resides in the neighborhood where said cattle are located, who shall examine said cattle; and the decision of said third person so selected shall be final as to whether or not physical evidence of the existence of such disease exist. The owner of any animal or animals reacting to the tuberculin test, and showing physical evidence of tuberculosis, may, in the discretion of the veterinarian selected by the Fiscal Court, as aforesaid, be given a reasonable time in which to prepare such animal for slaughter, provided said animal is isolated from other cattle (of the same kind), if such reacting animal, in the opinion of said veterinarian, would, when slaughtered, be fit for food; but, if such animal, when slaughtered, would not, in the opinion of said veterinarian, be fit for food, then the same shall be destroyed at the expense of the owner thereof."

Section 2 declares:

"That hereafter the State Board of Health shall not apply, nor cause to be applied by any officer, agent or employe, the tuberculin test to bulls, cows or calves owned and held in this State."

"Section 2a declares:

"That no city nor town shall apply or cause to be applied by any officer, agent or employe, the tuberculin test to bulls, cows or calves owned or held in this State or require same to be applied, except as indicated in Section 1 hereof, to any cows from which milk or other dairy products are furnished to said city or town."

WOULD ANNUL OLD LAW.

It will be seen that Senate bill No. 56 annuls the law which has been in force so many years, and that the board which has had so much experience and which has so successfully fought tuberculosis and applied the tuberculin test is deprived of the power and authority under the law which it has so long exercised; and it will also be seen that cities and town that have been so well protected and from which tuberculosis has been entirely eradicated are, under the proposed law, deprived of the safeguards and protection heretofore enjoyed.

"It should be observed that the bill under consideration provides that, in the event of disagreement between the owner of a cow and the county veterinarian, selected by the Fiscal Court, as to whether the cow shows evidence of tuberculosis or not, the owner shall have the right to select another veterinarian to examine the cow. If these two disagree they shall then agree upon a third veterinarian who resides in the neighborhood where said cattle are located, who shall examine said cattle, and the decision of the third person, so selected, shall be final as to whether or not physical evidence of disease exists.

"In the 120 counties of this State there are not more than ten counties in which this section of the bill could be carried out, where three qualified veterinarians could be found. In the majority of the counties of Kentucky there are no qualified veterinarians.

"It should be observed also that the bill under consideration required the veterinarian appointed by the court to discover physical evidence of the existence of tuberculosis in the cattle before he is authorized to take any action whatever.

TUBERCULIN TEST RELIABLE.

"It is a well-settled fact that tuberculosis cannot be recognized in cattle during the early stages, and, in fact, it cannot be detected physically until it is in the very last stages, and has been spreading the germs of the disease for one or two years. Drs. Melvin and Hickman, who have had a large experience in examining animals which were slaughtered after the tuberculin test, and who are accepted authorities on this subject, say it is impossible to detect tuberculosis in cattle ordinarily by physical examination. The tuber-

culin test, in the hands of a competent and experienced man, is declared by all authorities to be more accurate than any other method of detecting tuberculosis; the Government records show that it is accurate in 98 per cent. of the reactions obtained, and it does not harm healthy cattle.

"The following statement made by members of the Lexington City Board of Health, is conclusive on this point:

"Acting as committee from Lexington City Board of Health to investigate most advanced and practicable health methods, we have given careful attention at the National Capital to milk control, including the tuberculin test. We have carefully gone over the facts among the actual workers in the Public Health and Marine Hospital Service, Bureau of Animal Industry and Washington City Health Department, and find these workers unanimous on following points:

"A—Milk from tuberculosis cows can and does infect children, especially babies. The infection so produced is often latent, but may break out in virulent form in latter years.

"B—Physical examination, while necessary, is wholly insufficient to detect many cases of actual virulent tuberculosis in cows, and the tuberculin test is the only safe and reliable test now known.

"C—Ten dairy herds in the District of Columbia, which passed a physical examination, were found to be supplying tubercle germs in the milk capable of producing tuberculosis.

"D—The tuberculin test, according to Dr. Melvin, Chief of the Bureau of Animal Industry, has eliminated tuberculosis from the dairy herds of the District of Columbia.

"W. O. BULLOCK,

"N. R. SIMMONS,

"R. M. ALLEN."

OTHER TESTIMONY.

"I received to-day the following letter signed by the Commissioner of Agriculture of Tennessee and the State Livestock Inspector of Tennessee:

"A copy of Senate bill No. 56, now pending in your General Assembly, has been received by this department. We have carefully examined said bill and consider it a step backward in livestock sanitary control work and have no hesitancy in saying should said Senate bill No. 56 become a law we will at once promulgate a rigid quarantine order against the State of Kentucky until such time as this bill is either repealed or revoked. We trust you may see your way clear to prevent this bill becoming a law.

"(Signed), T. F. PECK,

"Commissioner of Agriculture,

"G. R. WHITE,

"State Live Stock Inspector."

"I know of no higher authority on pure food, drugs and health than Dr. Harvey W. Wiley, who for many years has been Chief Chemist of the Bureau of Chemistry in the Agriculture Department at Washington. In a letter received by me from him he said:

"My attention has just been brought to an act which has passed the Kentucky Legislature regulating the inspection of dairy herds and milk in the State of Kentucky. I hope I may be able to reach you with this letter before you make up your mind to sign this bill. It seems to me that it is one of the most objectionable pieces of legislation that it has been my ill fortune to ever see. It takes away from the State Board of Health authority for the inspection of herds of cattle and places it in the hands of veterinarians selected in each county and not one of whom may be an expert in such matters. Further than that it is very likely that there are many counties in Kentucky where registered veterinarians with an expert knowledge do not reside and in such counties no inspection could be secured. Worse than this, it provides that no inspection shall be applied except where there are physical signs of disease which are unmistakable. Experience has shown that very few cows will reveal their tuberculosis condition to a physical inspection, but that these animals when subjected to the tuberculin test or when slaughtered are found to be seriously affected with the disease. The difficulties of securing an inspection in the way the law proposes are extremely great. Instead of having one competent board—namely the State Board of Health—to supervise it, there would be one for each county, and it stands to reason that most of them would be highly inefficient and unfit for the service. Still more objectionable is that part of it which deprives the State Board of Health of its present power and especially that section which will prevent any town or city of the State of Kentucky from protecting itself against tuberculosis milk.

"(Signed),

H. W. WILEY."

"I have received petitions from boards of trade, commercial clubs and individuals scattered throughout the State, protesting against Senate bill No. 56, but I will not include them herein.

"The Legislature of Kentucky at its last session enacted a law providing for a State Tuberculosis Commission. I regarded that as splendid and necessary legislation and I approved the bill; it marked a new era in the intelligent care for the health of the people; but many benefits promised in that legislation would be counteracted if the bill now under consideration should become a law.

"For the reasons herein stated, I cannot sign Senate bill No. 56 and I disapprove it."

ORATION IN MEDICINE

MEDICAL IDEALS FOR THE EVERY-DAY DOCTOR.*

By W. W. ANDERSON, Newport.

The ideals of to-day are the history of tomorrow in the embryo.

Who better than the man of medicine have high ideals? Who better than he may anticipate the history he is helping to make? Who may look back to the history of the past with such pride in his profession? If we may judge the future by the past, if the deeds that men have done are a guide to what they may do, if the record of other days is an inspiration for days to come, if a noble heritage oblige us to nobility, then how great heritage debt to the past! How deep is our duty to the present! How lofty is our inspiration for the future!

Every great movement for human welfare in promoting health and vigor has been instigated, advocated and carried to success chiefly by the medical profession to its own great loss, and often in the face of bitter opposition from the people who were to be benefited. The whole pathway of medical research and progress is marked by the bloody footprints of the martyrs of science—a noble martyrdom as lofty as any the church can boast. Vesalius was persecuted because he dared to study the dead body that he might know and heal the living. Jenner was ostracised and pictured as a devil incarnate. Harvey was described as an infidel. McDowell was threatened with criminal prosecution. Jeffries was mobbed. Flexner is branded a monster. Carroll, Lazear, and others, died to prove the cause and secure the prevention of yellow fever, and the government took twelve years to grant a widow's pension for the service.

No other calling or profession has such a record of constant and unselfish devotion to humanity. When the great Judgment Day shall come, Medicine may stand erect and humbly unabashed, while even the Law and the Church must hang their heads, for Medicine has always been the friend of the people. The Law, designed to safe-guard the liberties of man, has often riveted the fetters of his slavery; and the Church, ordained to give men that highest truth which shall make them free, has at times so far forsaken her high behest as to declare the cruel yoke of the oppressor holy and heaven-sent. No such charge can be sustained against the healing art.

Does some one say "How about the quack doctor?" How about that insatiate vampire

that lives by the blood of its victims—that unmitigated villain who robs the foolish and the suffering of money and of life itself? Are we charged with his deeds? Better charge Christianity with the hypocrite. For have not we cast out the quack? Have we not ostracised him? He is none of ours. And when we have done with him, has not the protecting arm of the Law been thrown about him and is he not received into the bosom of the Church? Does he not sit in the congregation of the saints, and do not even your religious papers befoul themselves with his lying and disgusting advertisements? Have not the courts again and again given him the advantage of every known technicality and quibble that he might not have impaired his most sacred liberty of fleeing the people? No, he is none of us. Some of us have been regarded as unorthodox in religion because we found difficulty in believing in a burning hell; but we are coming around all right. We had to put fire and brimstone back into our creed, for we had no other suitable way of finally disposing of the quack doctor.

What is the spirit that animates the medical mind and must always animate it from time immemorial unto the end of history? Not the greed of gold. The average annual income of Kentucky physicians (and they are as good as others) is less than \$1,000. There is hardly a doctor anywhere in the profession who could not instantly double his income, if he but adopted a code of morals that is daily in practice and accepted in the business world. Not the fanfare of fame. Even the greatest among us will be overtaken by his epitaph long before his name is heralded among the people. Not the pride of power, for such power as the doctor attains is exercised for the public good, hampered by political and personal indifference or hostility. Ask Dr. Wiley about power. And yet Medicine goes on healing and preventing diseases, in the main unmindful of money, forgetful of fame, and puny in power.

Do you remember Him who looked down from the slopes of Olivet on the holy city, and wept, and how He stretched forth his hands and said: "Oh! Jerusalem, Jerusalem, thou that killest the prophets and stonest them that are sent unto thee, how often would I have gathered thy children together even as a hen gathereth her chickens under her wings and ye would not!" These were the words of Him who was known as the "Great Physician." If the humane and benevolent spirit that pervades the medical profession could be gathered into one great personality, then would that great beneficent soul of Medicine look down on the suffering world and weep, saying: "Oh, erring sick, and sorrowing humanity! How have I longed to bestow on you

*Oration in Medicine, Kentucky State Medical Association, Paducah, October, 1911.

the boon of health and vigor and life abounding and ye would not!"

Your call to the service of the healing art is not the call of wealth, or fame, or power, or popular favor, or personal aggrandizement, or social distinction, or ease, or comfort, or long life. It is a call to war; a life-long enlistment on the side of humanity in its grim struggle with disease and death.

Man enters the world wailing and leaves it with a moan, and punctuates the journey from the cradle to the grave with many a cry of distress. He who deftly launches the traveler on the sea of life, who safely pilots the voyager through its storms and stress, making him fit for his seamanship until his bark is gently beached on the shores of eternity, has a great office to fill. So to conduct the advent of a new life as to make it safe in itself and free from damage to its maternal source is an important duty. To act as the counselor and guide of that new life in all matters physical, and to have a large share in shaping its mental and moral destiny, is a great task. To marshal the vital forces of that life and take command in its fierce battles with disease and death is a large responsibility. So to lead that life as to free it from self-destroying follies and lift it above foolish fears and superstitions, clearing the way for the development of its best powers and promoting its efficiency, is a lofty labor.

This is the work of the every-day doctor and it is a man's work, worthy of great men for its doing.

Man is never born great except potentially; nor can true greatness be thrust on him. It can be attained only by achievement. The man who habitually and heartily measures himself against the task before him is sure to

"Grow each day and hour

Into his life's potential power."

And the limits of that power, even to the every-day doctor, who shall set?

Our task calls for the active, attentive use of our best powers. We are not only to perceive what is thrust on our senses but to seek; not only to know what is forced on us by sight or hearing, or contact, but to look, listen and feel. The amount of knowledge acquired by the senses, its clearness and its permanence will depend largely on whether the senses are actively seeking knowledge or only passively receiving it. The same is true of the other faculties. If we allow our minds to drift and our conclusions to form themselves, they will be shallow, uncertain and unsafe. The matters we are called on to judge are far too important for this. They demand that our judgments be based on broad and thorough observation, careful comparison, and sound reasoning, the result of trained faculties actively at work. The best trained mind is that one

which, in the largest percentage of instances, automatically does its best, which does not need to be whipped up in each case to do good work, but has made thoroughness a habit. There are great difference in the original endowment and in the training of medical men, but these differences are not greater than those which result from experience. A man will either use and thereby improve his talents, or neglect and lose them.

The every-day practice of medicine is eminently fitted to the most of any man if he but gives himself devotedly to the work for its own sake. Herein lies a large hope for the every-day doctor and the mediocre man. Look at the illustrious names that adorn the pages of medical history. It is nowhere recorded that they were born great. Their glory was not gratuitous. Their schooling was not superior. Their opportunities were not larger. But they had great problems to solve even as others. They had mighty difficulties to overcome even as all physicians. They had sore needs to supply, even as you and I. And they measured their littleness mightily against the mighty force of ignorance, disease and death. They realized the worth of the physician's work and labored worthily. As workmen needing not to be ashamed they lived the every-day life on a high plane. With extraordinary energy they attacked ordinary duties. With uncommon concern they cared for their common cases. With patient persistence they solved and proved their problems. With a devotion to duty amounting to a holy zeal, they loved even their unlovely tasks and performed them with a thoroughness that lifted their common lives above the common things of life and grew in them the character that challenges the admiration of the world. Out of the every-day of life came to the medical profession a John Hunter, an Ephraim McDowell, a Robert Koch, an Oelsterlony, an Osler, a Murphy, a Mayo, and a multitude of others; and by what means? Can you imagine Laennec making a chest examination through a silk waist? Or Trousseau content with feeling the pulse and looking at the tongue? Or Sims satisfied with the surgery of his day? Or Cabot taking the patient's word for a diagnosis? Or Gorgas accepting his office as a sinecure? These are they that "waxed valiant in fight, out of weakness were made strong."

The every-day doctor may feel that they were men of very large natural ability and that we are not to be measured by them. They were giants, and we may be pygmies, but, mounting to their shoulders, we can see further than they. It is not necessary that we be great; it is necessary that we be faithful. The great men of medicine did not start out to

become great or famous; they simply did their work well and grew; for they had at hand the very best means of growth, even as you and I. They sat at the feet of the masters in studying their works, even as you and I are privileged to do. They touched hands with the best men of their day in their journals and associations, and much more may we. The race-long cry of suffering humanity assaulted their ears, as it comes to ours, and they set about its relief without stopping to appraise its money value or its offering of fame.

If any man in medicine will do that, the time will come when the profession, if not the whole people, will discover developed in him whatever greatness was potential in his endowment. Only let him not be easily content with present attainment. Let him feel that he has matriculated for a life-long course in the great university of practical experience, where every patient is a study, where every symptom is to be searched out and traced to its origin and weighed as to its significance, where every examination is an exercise in skill, every operation a training in technique and every prescription a drill in sound therapeutic reasoning.

The school of experience is proverbially expensive. The patients of the thoughtless doctor will find it doubly so; for he goes on repeating the same blunders, overlooking the same observations, reaching by the same reckless reasoning, the same careless conclusions, doubtful diagnoses, and "shot-gun" and unknown ready-made prescriptions. Such a man, profiting little by experience, drifts or blunders through his own and his patient's lives from his observation of obstetric positions as "head-first" or "feet-first" to the death report of "old age."

The great minds of medicine were not so made, nor did they come by chance. The practice of medicine has never been greatly raised by accident or freaks of fate or strokes of genius. The great men of medicine were just hard, earnest and capable workers. They grew great by growing into the greatness of their task.

There is need that medicine grow into the greatness of its task. Great things have been accomplished, but greater remain to be done. There was a time when epidemic disease swept over the face of the earth like a devastating frost and human life withered before it like the flies. Well did the psalmist speak of "the pestilence that walketh in darkness" and "the destruction that wasteth at noon-day." For the tragedy of bubonic plague, smallpox, syphilis, cholera, malaria, yellow fever, diphtheria and cerebrospinal meningitis are written large in the closed chapters of history.

Medicine has done so much that we occas-

ionally hear the opinion expressed that the doctor will soon lose his occupation entirely by reason of medical advance. That were indeed a consummation devoutly to be desired, but offering no early hope of attainment; for every great discovery in medicine has opened to the doctor a dozen doors of opportunity for every one it has closed.

Phagocytosis, so far from being a finality on resistance, has opened to view a long vista of agglutinins, opsonins, lysins, bacterins, vaccines, side-chain theories, complements, etc., and the end is not yet.

Ehrlich presents a new remedy which may cut short the prolonged treatment of syphilis, but in so doing he opens to research the great field of chemotaxis.

Lord Lister developed antiseptic surgery and so far from finishing surgery, it has filled the world with surgeons.

Medicine still has a great field for advancement. Tuberculosis has not surrendered. Measles and whooping-cough are still serious and universal scourges. Cancer remains the scandal of medicine. Gonorrhea and wild oats continue to be sown together and to yield their bountiful crops of disaster. The field of mental and nervous disease is still largely a jungle of unknown horrors. The internal secretions are unsolved problems. Auto-intoxication is only a tattered cloak for our ignorance. Pneumonia baffles us very much as it did the doctors of ten centuries ago. The acute and chronic joint inflammations and degenerations are in a blur of uncertainty. Kidney disorders and arteriosclerosis await elucidation. There is much territory for medicine to explore and still more to conquer.

Great as is the call for the advancement of our science, the demand for improvement in our practice is still greater; for our science is eagerly and earnestly using every means at its command to solve the mysteries of the unknown, while our practice is falling far short in applying the truths already revealed.

When the science of medicine has presented a new means of accurate diagnosis, or developed a better treatment, or evolved a surer prognosis, or offered a safer prophylaxis, it would seem reasonable that these discoveries should immediately appear in practice and rapidly become universal in use. It would appear natural that the science and the art of medicine should walk hand in hand; that theory and practice should keep step in the onward march of medical progress.

The world has a right to expect much. If my child is ill or injured, I desire that the art of medicine, as practiced at his bedside, shall apply the best that world-wide medical science has to offer, and I hear the voice of one

saying, "Whatsoever ye would that men should do to you, do ye even so to them."

In only one department of practice is our art following closely in the footsteps of science—the department of major surgery. The other specialties are lagging noticeably, and general practice (the work of the every-day doctor) is so far in the rear as to create some doubt whether he belongs to the profession or only happens to be traveling that way.

The surgeon leads because his work is spectacular and is done in the lime-light of publicity; because it is constantly reviewed under the fairly competent criticism of the general practitioner; because it commands a fee that supplies the means of good work; and because the surgeon occupies a limited field which he can cultivate intensively and in which he can keep up to date and become highly proficient. The same reasons hold good, but to a lesser degree, in the case of the specialists. The work of the every-day doctor is of the every-day of life, attracting little notice and reviewed by no authority nearer than the recording angel, or more capably critical than his own conscience. If well done, it is shamefully underpaid, and his field of labor is so extensive that intensive cultivation, proficiency, exactness, and keeping up to date, are impossible. Not much is exacted at the hands of the every-day doctor. His clientele does not require much and is not competent to judge whether he gives little or much. The demands of the law are small, only asking "ordinary care and diligence" and conscience is almost as easily satisfied.

But there is a call to higher things and eager men will harken, earnest men will hear, and honest men will heed. It is heard in the voice of scientific medicine, whose every established truth is a prophecy of good to humanity that pleads for fulfillment. It speaks in the tones of the healing art as she asks that the most beneficent task ever entrusted to human hands be well done. It comes to us in the world-old and ever-present cry of human need. It makes its mute appeal from the silent graves of the untimely dead that ask of us their rightful years cut off. It challenges us in the words of Him who said "What do ye more than others?" It upbraids us with the dupes of quackery, 99 per cent. of whom have slipped through our hands unhealed and unsatisfied. It stirs in the life of every man whose heart throbs with the joy of battle and whose mind is uplifted by the power of the ideal. What shall be the response of the profession and especially of the every-day doctor?

If we are to share in the conquests that await the advance of scientific medicine, it is necessary that we be equipped with broader knowledge, surer skill and riper wisdom.

The physician is in need of a broad general knowledge of the whole medicine. Only so can he escape the egregious blunders that grow out of narrowness of training or experience. Disease is not so exact in localizing itself or its manifestations as to warrant exclusive specialism. Every one of us should be able to see and understand far more than we can do. We may not be able to make a blood-count, or handle the X-ray, or use the cystoscope, or analyze the stomach contents, or remove an appendix or definitely determine a heart lesion, but we should know the principles on which each of these procedures are based, the field for usefulness of each, and the man who *can* do the work; and that man ought to be in easy reach.

The man of widest knowledge in medicine to-day is the every-day doctor in general practice, and yet the times demand even of him that he broaden his field of vision. Even more insistently does the times demand that he narrow his field of work. Medicine has grown far too great for one man to cover the whole field and do it well. The every-day doctor has undertaken too much and the consequence is that he cannot give, in many of his cases, the efficient service that present medical science demands. Nor can his efficiency command the fees that the specialist receives and deserves.

The every-day doctor must do some specializing. He ought to serve his patients in every case in which he is prepared to render as good service as is available to them. If, in addition to this, he will devote himself to the special study of the chest, he will in time become the neighborhood expert in that field. If his medical confreres will do likewise for the alimentary canal, the genito-urinary tract, nervous disorders, pediatrics, general and emergency surgery, etc., each will finally become the local authority in his particular field of general practice. He will then be able to render a better service in some one line and to command a better fee because he will be worth it. His colleagues, recognizing his special ability will call him oftener in consultation, thereby giving their patients a better service, the doctor a better income, and the profession the uplift of a better mutual understanding. At present we are confronted, in every well-populated community, with the paradox of too many doctors and too little efficiency of medical service. Let the every-day doctor, without giving up his general practice, specialize in some department of his work and this disgraceful paradox will tend to correction.

Consultations ought to be more frequent, and they would be if some near-by doctor were fitted to act as consultant. If the every-day doctor would so fit himself, he will improve his

standing in the profession, increase the respect in which he is held by the public and, what is equally as important, enhance his own self-respect.

It is not necessary or desirable that the every-day doctor undertake to displace the present-day specialist; nor ought he to look with envious eyes on the opportunities and privileges the specialist enjoys, for the narrow garden spots of specialism are well occupied and cultivated almost to the limit of productiveness, while the broad fields of general practice, now neglected, are fallow and inviting to intensive cultivation.

The greatest opportunities in the healing are to-day are waiting at the hand of the general practitioner; 95 per cent. of practice applies first to him and it is his to take what he will, his to have and to hold, if he will but prove himself worthy to have and competent to hold. Only let him not try to grasp everything, lest he show himself unable and unworthy to hold anything. Let him select so much and such kind of practice as he can serve with adequate art, commensurate with the best medical science has to offer. In cases in which his knowledge or skill are not up to that standard, let him seek aid in consultation, or send the patient to the man who can render the necessary service.

When the every-day doctor has learned to excel himself and others in something, he will begin to experience the pleasure of leadership, the distinction of success, the joy inherent in good work well done and the profits that in time accrue to worth.

When by doing less he has learned to accomplish more, when his skill in something has made him unwilling to do anything unskillfully, when his art is treading on the heels of science, then will medical science hurry forward to new conquests and the spirit of the healing art will go forth among the people who too long have "suffered many things of many physicians" in vain, and many will touch the hem of her garment in well-founded faith and be made whole and Medicine will find her rightful place in the esteem of men. Is this too good to be true? The answer rests with you and me, for in the Providence of God and the progress of medicine, there is nothing too good to be true.

Large Bilateral Bartholin Cysts.—Weiner's case presents a number of interesting features, the fact (1) that the cysts were bilateral; (2) their size, 118 and 125 cm., perhaps the largest on record; (3) the marked distortion and stenosis of the introitus, and (4) the rapid growth during pregnancy. This last feature is explained by the occurrence of hemorrhage due to the local congestion incident to pregnancy and the trauma of attempts at coitus.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicines. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A. Council on Pharmacy and Chemistry for inclusion with "New and Non-official Remedies." Under "Reform in Medicines" appear matters tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

THE VALUE OF PERISTALTIC HORMONES.

C. D. Aaron discusses hormones in general and the peristaltic hormone in particular. In regard to the latter he says (*Jour. A. M. A.*, Feb. 10, 1912, p. 407):

The peristaltic hormone has the capacity of stimulating the peristalsis of the intestine. It was found at first in the mucous membrane of the stomach, later in abundant quantities in the spleen; and it has been used in chronic constipation and in acute paralysis of the intestine. But the treatment is not altogether without distress, for it frequently causes pain and fever. If used for therapeutic purposes this peristaltic hormone must be introduced intravenously or intramuscularly and its absolute sterility must therefore be made certain. It has, in fact, been found that its intramuscular introduction produced pain and a rise of temperature, and the intravenous method is being preferred owing to the fact that it reduces the pain, fever and discomfort to the patient.

The observed fact that the hormone stimulates intestinal peristalsis, led quite naturally to its employment in chronic constipation. In spastic constipation we have an overstimulation of the intestine and the use of the hormone in such cases is, of course, irrational. In the atonic form, however, the hormone becomes valuable. Zuelzer reports success in 71 per cent. of many cases of chronic constipation, in which evacuations had previously not been possible for a period of years without cathartics or enemas. He feels himself justified in urging that, in the light of the discovery of the peristaltic hormone, the whole subject of constipation be revised. He suggests two theories with regard to the nature of the

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

therapeutic effect of the peristaltic hormone. In the first place, in cases of chronic constipation we have a complete absence of the normal production of the peristaltic hormone or a quantitative insufficiency of it. When peristaltic hormone is introduced, it stimulates the beginning of a normal elaboration of it in the body. And in the second place, it may be that the stimulus for the start of the intestinal peristalsis in atonic chronic constipation is produced when the hormone is administered, by the intervention of the nervous system. The hormone may exert a specific stimulant action on the abdominal ganglia. The ability to convey the stimulus may have been disturbed or dulled. An artificial saturation of the organism with peristaltic hormone may vigorously stimulate the nerve-cells and enable the body to react again to the normal stimuli.

Zuelzer uses 40 c.c. of peristaltic hormone for an adult and 20 c.c. for children. The injection is made only once and the median vein is the best place for it. The skin is prepared aseptically and an Esmarch bandage applied on the upper arm to make the vein prominent. The fine needle of the syringe is introduced into the vein, the Esmarch bandage loosened and the contents of the barrel of the syringe are slowly forced into the vein. The needle is removed and a slight pressure with gauze is applied to the point of entrance. A small piece of adhesive plaster is then applied. Usually no reaction ensues. It is advisable to follow up the injection with one dose of castor oil. It serves as a lubricant while the hormone induces the normal peristaltic action. As against other remedies employed in chronic constipation, the peristaltic hormone has the superior merit that, having started evacuation, there is no need to inject more of it.

Henle, Saar and Unger studied the action of peristaltic hormone, in postoperative intestinal paresis, in the case of epileptics who had previously suffered from chronic constipation, and in the case of an almost moribund patient, with total intestinal paresis, with intestinal loops partly obstructed by inflammation, and proved that the peristaltic hormone is an innocuous substance. Several cases of ileus, in which intravenous injection of the peristaltic hormone was made in patients who were advanced in years, and who had some time previously been operated on, show that peristaltic stimulation produced by the hormone is not violent and causes no grave disturbance even if there is organic derangement and obstruction.

In view of the optimistic opinion apparently held by Aaron it should be noted that in connection with the discussion of the proprietary preparation, hormonal, in New and Non-

official Remedies the Council cautions that the use of peristaltic hormone is still in the experimental stage.

MRS. EDDY AND THE NATIONAL LEAGUE FOR MEDICAL FREEDOM.

Mrs. Mary Baker Eddy, the founder of Christian Science, years ago, forbade her followers to enter into any league with "occultists, mesmerists and vendors of patent pills." If she were alive to-day, she would undoubtedly have prevented the organization of which she was the head from making the fatal tactical blunder of an alliance with the pseudo-medical cultists, sectarians and faddists, patent-medicine fakers, food adulterators and quack doctors, who go to make up a part of the motley crowd which calls itself a "League for Medical Freedom." This injunction on the part of Mrs. Eddy, evidently overlooked by her successors, has been pointed out by Mrs. Augusta E. Stetson, insurgent Christian Scientist and ex-reader in one of the leading eastern churches of this cult. Mrs. Stetson says, according to Rochester (N. Y.) *Evening Times*, that such an alliance is in direct violation of the injunction of the founder, who wrote, "By rendering error such a service, you lose much more than can be gained by mere unity on the single issue of opposition to unjust medical laws." It has been recognized for some time that the alliance of "Christian Science" with all sorts of medical fads and fakes was rendering error a great deal of service. In fact, it has generated about as much error as a single organization possibly could. Whatever one may think of Mrs. Eddy's religious and philosophic vagaries, no one familiar with her life has ever questioned her practical shrewdness and far-sightedness, says *The Journal of the American Medical Association*. That those who have succeeded her as leaders are not her equals is not strange. History is full of causes and crusades which, after the death of the prophet who inaugurated them, went to pieces through the blunders of disciples who succeeded to the leadership.—(*Jour. A. M. A.*, Feb. 24, 1912).

BODY CELLS AND FOOD SUBSTANCES.

"The cells of our body never learn what the character of the food which we eat really is." With this sentence delivered at a recent meeting of Swiss men of science, Professor Emil Abderhalden has concisely defined a modern view-point of nutrition which is rapidly becoming prominent. Before they leave the alimentary tract the foodstuffs which we eat are broken up into fragments that serve as the real food of the body. Complex carbohydrates are resolved into sugar; fats are split

into glycerol and fatty acids; proteins yield an aggregation of characteristic substances. Indeed, the main function of digestion, according to *The Journal of the American Medical Association*, is to put these comparatively simple "building-stones" at the disposal of the internal tissue cells so that they can select, or further rearrange them as the special functions require. Whether it is meat or cereals that we eat is, after all, largely a matter of indifference, for they all furnish similar digestion fragments, so long as the digestive process perform their duty.—(*Jour. A. M. A.*, Feb. 24, 1912).

ANESTHESIA AND ANESTHETICS.

Probably the first successful local anesthesia was produced by the use of ice, or salt and ice. The next step in local anesthesia was the freezing with ether of the part to be operated on.

A later remedy included in the same category of freezing mixtures is ethyl chlorid. This is offered under the proprietary name Kelene. When this is opened, the container being held in the hand, the warmth of the hand heats the ethyl chlorid in the bottle so that it emerges from the metallic opening in the form of a fine spray, which, when held several inches away, freezes the part with which it comes in contact.

Local anesthesia did not attain very marked popularity, however, until Koller, in 1884, demonstrated many of the anesthetic properties of cocain, particularly its action on the mucous membranes of the eye. Many experimenters followed the lead of Koller and extended their experiments in many directions. It was soon found that while solutions of cocain obtunded the sensibility of mucous membranes, they had no effect on the unbroken skin; but injected beneath the skin by means of a hypodermic syringe they produced abolition of sensation.

As the knowledge of the action and effect of cocain increased, it was found that, if used too freely, it often produced alarming symptoms. This was especially the case when the drug was administered hypodermatically. It was then soon discovered that if the circulation of the part to be operated on was brought to a standstill by the application of bands, applied for instance around the limbs, if that happened to be the seat of operation, a smaller quantity of cocain was necessary to bring about anesthesia, the anesthesia continued longer, and if the circulation was then restored gradually, the effect of the drug on the entire body was less likely to produce unpleasant symptoms.

At first the strength of cocain usually employed was a 4 per cent. solution in distilled

water. Later, it was found that a 2 per cent. solution was effective, and still later solutions of less than 1 per cent. were found to act satisfactorily.

Still further observations with cocain and other local anesthetics led to the conclusion that often the sensibility of the part might be sufficiently benumbed by the hypodermic injection into the tissues of sterile water. S. Gant, of New York, has, during the last ten years, advocated this means of producing anesthesia and has employed it especially in surgery about the rectum. He maintains that the water should be injected into the lower layers of the skin, and that it is only when the skin becomes pale and apparently edematous that the most efficient anesthesia is secured.

Among the earliest substitutes proposed was beta-eucain. In 1905, novocain was discovered. It can be sterilized by boiling without undergoing change. Novocain does not injure the tissues, does not interfere with the healing of wounds after operation, and is estimated to be from one-sixth to one-seventh as toxic as cocain. It may be used in distilled water or in a physiologic salt solution and it may be combined with a small amount of epinephrin (adrenalin, suprarenalin, etc.) This combination with epinephrin intensifies the action of the drug so that less is required than when the epinephrin is not used with it. The drug may be used in strength of one-half of 1 per cent. solution. On mucous membranes its action is inferior to that of cocain.

In 1907, quinin and urea hydrochlorid began to be used as a local anesthetic. For the production of such anesthesia injections of a solution of from 1-4 to 1 per cent. strength are used. (See N. N. R., 1912, p. 195). This produces a more protracted anesthesia than the other drugs mentioned, often lasting for several days. The drug may be dissolved in water or in physiologic salt solution.

Anesthesia by means of quinin and urea hydrochlorid has been used in operations on the tonsils with considerable advantage because it not only abolishes the pain, but also by the exudate of fibrin diminishes the tendency to hemorrhage. Local anesthesia has been used especially in operations for hernia, on the genito-urinary organs, exploratory laparotomy, abscesses of the vermiform appendix and of the gall-bladder.—(*Jour. A. M. A.*, Feb. 24, 1912, p. 554.)

CEREBRO-SPINAL MENINGITIS.*

By W. L. Mosby, Bardwell.

The subject assigned me by our committee on program is so broad and so important that we feel justified in considering only a part of the general family "meningitis" in your presence this morning, so we take the liberty of discussing the possibly most important form to-wit: "Epidemic Cerebro-Spinal Meningitis."

This much dreaded disease occurs sporadically as an endemic or as an epidemic and prefers the environments of the rural districts, but does not (as has been shown by recent epidemics in Texas) discriminate against or exclude the city dweller from its recruits.

Winter and spring months seem to favor its development and spread and those more exposed to the hardships of life and live in unsanitary surroundings with improper food and clothing, crowded tenement houses with its accompanying evils, favor its development.

It has been given many names from time to time, by different authorities, such as "spotted fever," "malignant purpuric fever," all suggested by the petechia, ecchymosis, erythema or purpura that may accomplish it.

The anatomic lesion and pathologic condition is sufficiently indicated by the term "cerebro-spinal meningitis," and is an infectious inflammation of the pia mater and arachnoid of the brain and cord.

Weichselbaum believes the diplococcus intracellularis meningitis to be the microorganism present and responsible for the disease and claims it to be found in the polymuclear leucocytes.

The meningococcus is found in the nasopharynx of healthy people exposed during an epidemic in about 50 per cent.

Passed Assistant Surgeon, R. H. Von Ezdorf, found in the present epidemic in Texas that out of 410 healthy persons who had been exposed to the disease, that 59.6 per cent. showed themselves to be positive carriers of the meningococcus and from cultures it showed 53.75 positive carriers. First examination, nose and throat both positive, 152; nose or throat one positive, 99; nose and throat both, negative, 170.

In the 239 cases reported by him in the P. H. Bulletin, Vol. XXVII (No. 8, ages were given as follows: under one year, 12 cases; 1 to 4, 30; 5 to 9, 41 cases; 10 to 14, 14 cases; 15 to 19, 27 cases; 20 to 29, 40 cases; 30 to 39, 23 cases; 40 to 49, 26 cases; 50 years and over, 15 cases, and ages not given, 11 cases.

Up to January 27th, twelve reports of the

*Read before the Carlisle County Medical Society.

State Health Officer gave a total of 550 cases, and 210 deaths occurring in 49 counties of the state, principally Dallas, Ft. Worth, Waco, Houston and remarkable to say not a case had occurred in San Antonio up to January 25th, this being one of the largest cities in the state.

More males were affected than females, and the mortality was slightly less in females than males. Weather conditions had been very bad, cold and rainy for two months, following a three years' drouth during which time water had to be shipped to Dallas for drinking purposes. A significant fact worthy of consideration was the prevalence of an epizootic of so-called "blind staggers" among horses that had preceded the occurrence of cerebro-spinal fever in Texas this time and it might suggest the possibility of its occurrence in our locality soon as we have had a similar experience with stock this season. In Oklahoma state this epidemic reports from December 1st, 1911 to January 25th, 1912, 72 developed cases with 2 suspects and a total of 36 deaths in 14 counties. State and local authorities acting in concert in its control, by isolation, quarantine, disinfection, bulletins on sanitation, etc. The spinal fluid was examined by Dr. A. E. Thayer, Professor of Bacteriology in Baylor University of Medicine and Pharmacy; Dr. Abraham Sophian, of the Research Laboratory New York; and Dr. Nash, Health Officer of Dallas, carried out the treatment by use of Flexner's serum, giving a mortality of only 10 per cent. while the general mortality in the hospital was higher.

The meningococcus was found in the spinal fluid of all cases examined by Dr. Thayer.

Epidemics vary greatly as to severity and mortality varying from 20 to 75 per cent., being larger in children than adults.

SYMPTOMS.

In the fulminant form the onset is sudden and a chill will initiate the attack, its violence will suggest a grave condition, severe headache, stupor, disturbed by muscular spasm, great depression, and even collapse may early close the scene. In this form the temperature does not run high, usually, and the pulse may not exceed forty to sixty beats per minute, with feeble heart actions, labored breathing. Hemorrhagic extravasation frequently occurs in the form of purpuric rash before death ensues in less than twenty-four hours. I remember one case dying in six hours, and a young man in less than twenty-four hours.

In the ordinary form the disease develops quickly but with premonitory symptoms, such as headache, back-ache, and loss of appetite. A chill may usher in the real attack with vomiting and elevation of temperature (101 to 106.) Pulse is full and strong and later

becomes quicker and weaker. Vomiting is of the projectile or cerebral type. Pain is severe in back of head and neck, and there is a peculiar stiffness in muscles of this region, aggravation of pain on movement of head or body. There is intolerance of light and sound, with hyperaesthesia of skin to touch. Children become peculiar, irritable and restless, delirium may occur early, and be maniacal or active in form, and after a few days is succeeded by stupor deepening into coma and death. Cheyne-Stokes respiration is sometimes present. Pulse becomes disturbed and runs away with slightest disturbance or movement of patient. Constipation is the rule, with so-called scaphoid condition of abdomen. May be albuminuria with polyuria.

No disease is more variable in its course nor deceptive in its character. It may terminate in a few brief hours, or suffering may be prolonged for a number of months.

Among the special diagnostic signs we will mention Kernigs. This is obtained by placing the patient in a sitting position with the thighs flexed at the hips, and legs partially flexed at the knee, the patient can not extend leg at the knee on account of the irritability of the nerve roots of lumbar and sacral region, caused by meningeal inflammation. Babinsky's reflex, is done by tickling sole of foot, causing a turning up of great toe, which is not uniformly present.

Abortive forms occur, and may exhibit sudden and severe symptoms but quickly abating without explainable cause. Again we may see cases so mild that only the presents of an epidemic would enable us to positively make a diagnosis. Lumbar puncture has been used both for diagnosis and treatment.

TREATMENT.

We should have a large room of uniform temperature, quiet, well ventilated, and moderately dark, a good capable nurse is of special value. Conditions favorable for mental and bodily rest are essential. Food should be nutritious, easily digested and given at regular intervals. Pain may be relieved by hypodermic use of morphia 1-4 to 1-2 gr., with atropia 1-150, or t. opii deodorized gttts. 5 to 30, with one to four of tr. belladonna may be given by mouth if preferred. Rest has always seemed essential to a cure in these cases. Restlessness may be controlled if not too severe by potassium bromide or ammonia, but its disturbing effect on digestion should not be overlooked. J. M. DaCosta uses hyoscyne hydrobromate for muscular spasm, or it may be relieved in some instances by phenacetin or aspirin, but weakness of the heart is a contraindication to their use.

For insomnia sulphonal or trional may be given but may prove inadequate in the severer

cases, hot baths are highly praised by some practitioners. F. M. Jewnin reports five cases all recovering by use of baths 99 to 104, and Alfred Walish reports seven cases with five recoveries from baths beginning at a temperature of 90 1-2 to 92 3-4, and adding hot water to bring it to 104 degrees, during its administration the ice-bag or cold water coil is placed on patient's head.

Bichloride of mercury hypodermatically in 1-6 to 1-15 gr. was used by Dr. J. D. Smith, late of Paducah, who claimed brilliant result but others failed to get benefit of this author.

Lumbar puncture antiseptically and properly performed is safe and gives at least temporary relief if nothing more, removing five to ten drams of fluid with an aspirating needle, two to three drams of a one per cent. lysol solution may replace the aspirated fluid and is recommended by some authorities. Antidiphtheritic serum has been used in the treatment of cerebro-spinal fever but results do not justify its administration. Antimeningococcic serum discovered by Flexner, of New York, has done more for these sufferers than any other therapeutic measure yet introduced. A report of one hundred and twenty-one cases injected between the first and third days gave one hundred and three recoveries (88 1-10), and of one hundred of first treated between the fourth and seventh day seventy-eight recoveries (78 per cent), one hundred and seven cases first treated after the seventh day, sixty-eight recoveries (63.6), so we are led to believe the benefits of early injections is clearly shown. It has also been shown that by this treatment complications are lessened, convalescence hastened, and sequela prevented for it has been demonstrated that the meningococci rapidly disappear under its administration.

CLIMACTERIC NEUROSIS IN WOMEN.*

By J. O. JENKINS, Newport.

The establishment of menstruation and its cessation are both marked by systemic disturbances peculiarly their own. A class of disturbances which while not apt to produce physical alteration of the organism, very often shadow the functional activity of an organ and set in motion processes which ultimately derange the general health. But all the ills that women may be heir to must not be laid to the change of life. Certain pathological conditions are apt to take place in those years, but that acute diseases are specially influenced, or that chronic ailments are especially modified by the climacteric is doubtful.

If we stop to consider the amount of the

accustomed volume of blood lost at each menstruation for years and now turned back into the circulation, we can fairly judge the effect of the heightened pressure on the system. The retention of the normal waste in the body stimulates nutrition and the woman generally becomes more plethoric. Controlling all nutritive functions however, we have the great sympathetic nervous system with its numerous ganglions sometimes called because of its importance the "abdominal brain." The gastric, abdominal and pelvic ganglions are in intimate relation with the generative organs and the sensory fibres of the spinal and cerebro-spinal system of nerves. Through them or to them are transmitted to the sexual center of the brain all the irritations and fluctuations of genitive sensation to be translated into a multitude of symptoms elsewhere in the body. The disorder created is somewhat similar to that produced by disease of the thyroid and the parathyroid. A nerve hypertension is produced and the whole economy is in a commotion. The menopause or climacteric in women denotes the end of her active sexual life. The retrogressive alterations of structures and function instituted operate as a distinct shock to an otherwise well balanced psychic nature, and a varied train of illogical and erratic complexities are precipitated upon a hitherto stable and amiable nature. The high nerve tension and hypersensitiveness of the emotions are responsible for explosions which run the gamut of psychic and neurotic diseases. The cerebral unsteadiness is also heightened very often by the toxins present in the body as a result of depraved metabolism. The presence of ovarian secretion or ferment has also some influence on metabolism and nerve tranquility. Headache is common and neuralgia affecting almost any structure of the body, may inflict great suffering for days at a time or periodically for hours only. The organ affected is normal but the pain is often very severe and the attacks may recur for some years after the menopause has been completed. Disturbances of vision, dizziness, faintings, convulsions, and unaccountable weeping add their vagaries to the load the woman must carry, while storms of temper, hysteria and sexual delinquency make life miserable for her friends and relatives. Perversions of sensation may make life a round of misery, in fact very few women pass through the menopause without at some time, experiencing the troubles due to hyperaesthetic irritations of the nerves of the skin. General or localized pruritis robs her of comfort in the daytime and of sleep at night. When the pruritis is localized around the vulva or anus the victim becomes unwelcome to her friends and an executioner to herself.

Her whole thought is to relieve the itching.

*Read before the Campbell-Kenton County Medical Society

and the thousand and one remedies do no good, it is scratch, scratch until the surfaces are raw and bleeding with no relief.

The pudic nerve is at fault and other things failing, its section offers the woman the best chance of cure. Often associated with or dependent on the pruritis is eczema of the genitalia. This in itself is not so serious for it can usually be much benefited or cured by a proper line of treatment.

One of the most unhappy features of the period of sexual involution is the mental unsteadiness which is precipitated upon the individual and of which she is often vaguely conscious. The unsteadiness may be nothing more than a sense of unrest, a desire to change place or occupation or may show itself in vacillations of character and motive. A sense of fear and impending danger may keep her continually on the alert and rob her nights of sleep until insomnia becomes a fixed habit.

The alterations of sexual habit in the married woman is occasionally very marked. From being prudent and conservative in her passion she becomes the opposite. Fear of pregnancy and child bearing have kept her within bounds, but with the menopause well past, she feels she may safely throw caution to the winds and, as a consequence, staid matrons of society thus afflicted absorb all the reserve sexual favors of the legitimate donor and then add zest to the pursuit of pleasure by straying into fresher and more youthful fields.

With some women it becomes a mania to associate sexually with numerous men, or to exhibit their naked bodies wholly or in part, to the view of their erstwhile admirers.

A step further and true psychoses develop leading to pronounced insanity of minor or major degree or to paranoia. The history of neurotic disease among the ancestors may frequently be developed in the examination of the patient. Church, Nervous and Mental Diseases, says: "There is a physiological commotion in the nervous system at the time of the cessation of ovulation and menstruation, a disequilibrium associated, even in normal individuals, with numerous neurotic manifestations, and, in such as have unstable organizations, attended with peril to the mental integrity. Melancholia, simple and hallucinatory paranoia of chronic character, and circular insanity are the forms of psychosis incident to the menopause. About four per cent. of the cases of insanity in women are due to the climacteric."

The insanity which develops during the unsettled period is usually of sexual type and presents itself perhaps more often in those who have borne no children and in the "old maid."

This is possibly the despairing protest of nature against race extinction, that the individual unit should die without descendants. The sexual dreams of the woman have not been realized. The unsatisfied sexual hunger or force in such, becomes intense under the strain, escapes the vigilance of conventionalism and floods the personality of the woman with a torrent of erotic desire of all grades of moral filthiness and degradation. Nature has unfortunately overshot the mark and produced disaster instead of a harmonious symphony of life. Fortunately some victims partially or completely recover their mental stability when the physical equilibrium has been restored. Closely allied to the graver psychoses are the accentuation of the development of foibles and eccentricities such as walking the floor while eating the meals or performing ordinary duties by uncommon methods. Such patients often complain of the sensation of a moving body within the abdomen, stomach or chest. Illusions and hallucinations may add to the general disorder and the woman frequently become the victim of the religious faker, the neighborhood busy-body or schemer promoting his own interests. A woman presenting features of this kind is also liable to attach too great importance to her bodily ailments and become morbid. More often is it true if she be of phlegmatic temperament, stout build and a good feeder. It is chiefly from this class also that we hear complaint of a weight at the epigastrium; of gastric distention; cardiac palpitation, and alternating hot flashes and chills. Reflexions of visceral distress not unfrequently produce nerve depression, and we consequently find a few in whom numbness of a portion of the body produces the fear of paralysis on account of the anaesthesias and parasthesias sometimes present. Thus the hand, fingers, arm or leg may "go to sleep," or show lessened muscular strength and activity. We believe this to be due to one of two causes. First, depressive alterations from accumulated toxins in the body structures obnoxious to the vasomotor system. Second, the exhaustion of muscle fibres in previous years by hard work, severe illness or childbearing. It is difficult to convince the woman that her fears of paralysis are groundless provided always, there is no history of syphilis.

Permit us to consider a pathological condition largely dependent on the reflex results of ovarian involution, the effect being produced on metabolism and nutrition and which is sufficient to impair the bio-chemical processes necessary to bodily health and structural hygiene. The patient is between 40 and 45 years, has taken on flesh rapidly the past year or two, menstruation irregular as to time and quantity. She is a hearty eater of rich

foods, sweets and has no objection to a glass of wine, beer or other liquors. She sleeps well at night and takes a nap after dinner if opportunity offers. Her skin and sclerotics are darkened; the tongue is large, flabby, indented at its margin by the teeth and covered with a yellowish-brown fur; the breath has a mawkish odor and eructations of foul gas come from the stomach; the intestines are distended and the belly tympanitic, there is constipation, scanty urination, breathlessness and a flushed face on attempting moderate exercise or on ascending heights. There may be headache or only a sense of oppression in the brain and a sluggishness in intellectual activity. "Billiousness," we say, and proceed to give a cathartic. Very good, but the whole train of symptoms indicate a toxæmia which requires a most thorough and prolonged housecleaning. If you dismiss the patient with a handful of pills, a few doses of calomel or a bottle of salts, you have given her a brief, temporary respite from worse ills. The case is one of lithemia dependent on the menopause and will surely surround itself with more serious complications if not followed up and eradicated. Just such cases have developed a diabetes, a Bright's disease, gall bladder infection or structural disease of the stomach, pancreas or duodenum.

DIAGNOSIS.

In considering ailments at the climacteric a decision will have to be reached between the menopause and its complications; a sickness occurring during the menopause, neurasthenia and central nerve diseases. The treatment naturally divides itself into three parts to meet the requirements of the three forms of derangement though sharp boundaries cannot be drawn.

The chief divisions are:

1st. Those patients presenting symptoms of lithemia.

2nd. Those presenting types of nerve derangement.

3rd. Those presenting evidences of exhaustion and malnutrition.

For the first class elimination should be the watchword until the tissues of the body as determined by proper tests are free from the toxins of a faulty metabolism. A carefully arranged diet from which much flesh food has been excluded, a limitation of the total daily food quantity, the substitution of bulky food articles of low caloric value for those of higher proteid percentage, acid and subacid fruit juices, green vegetables are permissible but no water-cress, cabbage, turnips or radishes should be allowed on account of the high percent. of mineral salts contained in them. Alcoholics, sweets, sugars, spices, much tea, coffee, chocolate and fats must be forbidden replacing them by the injection of one or two

quarts of water daily. A daily hot bath followed by a cold shower and brisk rub is very beneficial. A Turkish bath once or twice a week is also very helpful provided there are no contra-indications.

A brisk walk of from one to four miles each day will add much to the effectiveness of the treatment. As to drugs the salines alone or in combination with salicylate of soda, phosphate of soda, soda citrate and carbonate, lithia given in effervescent form or with carbonated water are particularly valuable. An occasional dose of calomel, comp. ext. colocynth, aloes, podophyllin, scammony, jalap or gamboge will aid the saline treatment and serve to clear the urine of the debris contained in it, and reduce the danger of gall-bladder infection.

Flatulence will cease, the acetone, butyric, sulphuretted hydrogen and other odors will disappear from the breath and the sensation of gastric and abdominal distension will cease.

The second class is the one most likely to exhibit the greatest variety of nerve disorder. The woman is often of emotional extremes with strong sexual desire which has been fairly well repressed or controlled. A different therapeutics is therefore required. The physical type of this class is the morbidly nervous hysteric of florid complexion. Attention will be paid to elimination and an effort made to relieve the patient of physical, social and mental irritation, by a change of surroundings hydrotherapy and judicious massage.

Intervals of travel, sanatoria and country life with relaxation and suitable occupation promote good results in selected cases.

All exercise should stop short of actual fatigue, and regular hours and habits must be encouraged or enforced. The diet should be digestible and consist of the lighter forms of flesh food, green vegetables, fruits and carbohydrates unless obesity is present.

Alcoholic stimulants and stimulating food must be avoided if good results are to be obtained. A one minute cold shower every morning materially aids in regaining nerve tone. As to drugs, a varied assortment may be tried sometimes with good success and many times with failure.

The so-called nervines naturally suggest themselves and valerian and its combinations have a reputation for those excitable attacks of "the nerves" approaching hysteria. Other remedies found useful are hyoscyanus, monobromide of camphor, cannabis indica, canium, glycerol phosphates, phosphoric acid, the phosphates and bromides of soda, strontium and nickel, assafoetida is an excellent remedy when given in large doses. Some cases where either the arterial pressure is high or the nerve excitement very great will respond best

to tr. gelsemium, bryonia, veratrum viride or belladonna.

Other cases are best relieved by coal tar derivatives, chloral or opium. Venesection, blue mass, blisters and opium were much in evidence in this and the previous class particularly if plethora was notable, by the practitioners of former days.

The remaining class presents to us the results of the rough usage of life on woman, the wear and tear of hard labor, of frequent child bearing and insufficient food perhaps, and who has seen the bright aspirations of her youth vanish one by one in the matrimonial sea. She is anaemic, nervous, disheartened and physically bankrupt. The line of treatment is obvious. Ease up the strain, provide plenty of nutritious food of high proteid value, recall to her memory the forgotten precepts of personal and household hygiene.

Entice her from the steamy soapuds to the fresh air of the parks or a country home. Give her a large portion of sunshine and a vacation from family affairs. Medicine she probably must have, and you will be quick to think of iron in its many forms, first one and then another combination.

Bland's mass, Griffith's mixture, Basham's mixture because it is both pleasant to take and contains the reliable tr. ferri chloride, arsenic, arsenite of iron, tr. nuc vomica, strychnia, manganese and bark tonics for their stimulant effects. Each has an important place in restoring the blood, flesh and nerve integrity.

Strive in this class to promote an increase of flesh just as in the first class you would endeavor to reduce the weight. Reach an equilibrium proportionate to the woman's stature and you will have gained an important point. Where nerve tension has produced much emotional erythema the corpora lutea or lutein given in five grain doses two or three times daily will be of much benefit, but should be continued for a month or more in decreasing doses. The pruritis and eczema of the vulva are almost always curable by the X-ray. In conclusion he will succeed best, who is successful in impressing on the mind of the patient that she can be cured, in other words, her full confidence must be gained, bear in mind, however, that startling cures must not be expected too quickly. Proceed then with a judicious and masterly hand submerging your vexation at a temporary defeat, and view your task from some other hopeful point of attack. Success will follow in the large majority of cases, and you will have the satisfaction and peace of mind of the one who conquers.

ACUTE OTITIS MEDIA; CAUSE, COMPLICATION AND TREATMENT.*

By W. J. THOMASSEN, Newport.

Earache, from time immemorial, has been considered by the laity and by many of the profession as a simple childhood complaint and all that was indicated in the way of treatment was an abundance of endurance on the part of the individual, plenty of hot rancid rabbit oil to instill in the external ear or perhaps hot tobacco smoke blown into the ear, providing a smoker was handy.

When nature came to the rescue and the drum membrane ruptured, the child experienced relief, and grandmother and her rabbit oil received the credit and the child went on to recovery or, more often, the individual was left with defective hearing, or spent the rest of his days with a discharging ear.

Pain located in the middle ear is nature's cry for help, and if recognized at the proper time and treatment instituted, the individual is not only saved much suffering, but the ear structure itself is prevented from undergoing changes that may render the individual hard of hearing, as well as causing him to have a chronic discharging ear that may shorten his days or at least, compel him to be an outcast from society.

In this day of preventive medicine, a large per cent of all middle ear complications should be prevented. The time to treat these condition is before the Eustachian tube is involved. In other words, treatment should be given to the child just as soon as any abnormality is discovered in the throat or upper air passages.

We now know that the majority of all ear conditions is secondary to some pathological condition in the throat and the lymphoid tissue in the vault of the pharynx is more often the cause of middle ear infection than all of the other structures of the upper air passages. The child with the snuffles has one of two conditions—either syphilis or adenoids, and I believe I am safe in saying, in private practice you will see ten children with adenoids interfering with respiration and nutrition to one with congenital syphilis. It is impossible for a child, with an obstruction due to adenoids, to properly take the breath, consequently nutrition is interfered with.

The hypertrophied or diseased adenoid tissue in the infant, is a frequent cause of tubal catarrh, and any interference with the ventilation or drainage through the Eustachian tube, exposes the middle ear to infection. The child is never too young for the removal of the obstruction from the post nasal space.

It is not proper to remove the adenoids

*Read before the Campbell-Kenton County Medical Society

from all children, but it is proper to remove the obstruction from all cases irrespective of age, if respiration or nursing is being interfered with.

The hypertrophied tonsil may in some instances be the cause of middle ear infection, either by acting as a culture media for bacteria or by the secretion of an abundance ofropy mucus that may cover the mouth of the Eustachian tube. It is the submerged or buried tonsil that is more frequently the cause of middle ear infection. It is this type of tonsil that causes pain along the Eustachian tube and referred to the ear during an acute inflammatory condition of the tonsil. The submerged tonsil is practically covered in its entirety by the pillars and by the plica tonsillaris, the crypts are unable to empty themselves and as they are filled with debris of epithelium and food they become the incubators for bacteria. This type of tonsil is bound down by the pillars and in the act of swallowing, the tonsil presses on the Eustachian tube, narrowing the lumen of the tube by direct pressure preventing free drainage and ventilation of the middle ear. Any inflammatory condition of the nasal chambers may cause middle ear infection, especially is this true if the posterior ethmoids or the sphenoids are involved. This is especially true should the infection of these cavities follow la grippe. The discharge from these cavities drop into the post nasal space, and the mouth of the Eustachian tube is constantly bathed in these secretions. One important point to remember is to warn the individual, with an acute head cold or one with a sinus involvement (and a large number of your la grippe cases will come under this head) to not forcibly blow the nose, for by so doing they are likely to force bacteria through the Eustachian tube into the middle ear, and by so doing set up either a catarrhal or a purulent otitis media.

We, as physicians, should convince our patients that it is not necessary to make a noise when the nose is cleaned, nor is it necessary to use any force, for every time force is used, the individual exposes himself to middle ear infection. If we, as physicians, could eliminate the forceful blowing of the nose, we will have prevented a large percent of all tubal and middle ear complications.

It is well to consider the anatomy of the Eustachian tube, that we may understand why this tube is involved in all middle ear infections following some pathological condition in the throat or nose. This tube is the wind pipe of the middle ear. It is about one and one-half inches long, the bony portion being one-half inch and the membranous being one-inch in length. The tube is of a double trumpet shape, the narrowest part being at the junction of the membranous with the

bony portion, this narrow portion is known as the isthmus, and all of the tube below the isthmus is made up of the same kind of tissue as that of the throat, and is covered with the same kind of epithelium, in fact the tube to its isthmus is really a part of the throat and all diseases of the throat may extend to the tube by continuity of tissue.

That portion of the tube above the isthmus is a part of the middle ear, the tube being of the same structure as the tympanum. Under ordinary conditions the membranous portion of the tube is in a state of collapse; during the act of swallowing or yawning the tube is opened, and air is admitted into the middle ear cavity. When, for any reason, the tube is not opened during the act of swallowing the air is not admitted, and the oxygen within the tympanic cavity is absorbed, and a vacuum or negative pressure exists, there is an increased blood supply to the parts; the secretions are retained and undergo changes; the tissue becomes thickened and you have your tubal or tympanic catarrh. The mucous membrane of the tube undergoes a thickening; drainage and ventilation are interfered with and any bacteria that may have found their way into the middle ear are retained. The increased blood supply, heat and moisture is favorable to the growth of the bacteria, and a catarrhal or a suppurative process is established.

The accumulation of even a small amount of serum within the middle ear if retained is likely to bind down the ossicles interfering with their free movement and possibly causing an ankylosis of the foot plate of the stapes in the oval window interfering materially with the individual's hearing. Should the patient escape ankylosis of the ossicles, the drum membrane may be retracted or thickened interfering with hearing and in many of these cases the tinnitus or ringing in the ear is very annoying to the patient.

Another symptom of tubal involvement is the sound of the individual's voice. He will tell you that he dislikes to hear his own voice for it sounds to him as if he was talking in a barrel. This is due to the unequalized air within the middle ear and as soon as this air pressure is equalized, or in other words, as soon as the Eustachian tube again performs its normal function, the trouble with the patient's voice will disappear.

The acute infections diseases are a frequent cause of middle ear complications. Measles, no doubt, is the cause of more tubal and middle ear complications than any one of the acute infections. The angina of measles spreads to the Eustachian tube by continuity of tissue. Measles is considered of so little importance by the laity, and in many instances a purulent otitis is established before

a physician is called to see the patient.

Scarlet fever is another frequent cause of tubal and middle ear infection, and in this disease the infection is caused by a very virulent organism, and in a large number of cases the antrum and mastoid are involved. The writer recalls a case that was referred to him one year ago, with a double purulent otitis. This child did not only have scarlet fever, but smallpox as well, the smallpox coming on before the child had fully recovered from scarlet fever. In this child, the double otitis undoubtedly was secondary to the scarlet fever. Nevertheless there was an involvement of the mastoid on one side, which was operated on with a complete recovery, and under the prolonged treatment, the other ear ceased discharging and practically normal hearing was restored.

Diphtheria may cause middle ear infection by the diphtheria membrane invading the middle ear by the way of the Eustachian tube, the Klebs-Loeffler bacillus being found in the middle ear after rupture of the drum membrane. Lagrippe also invades the middle ear, and as this is usually a mixed infection, much harm may be done to the middle ear structure in a very short time, many of the cases having mastoid involvement, and it is in these cases that bone necrosis is very rapid and frequently the lateral sinus is denuded of all of its bony covering. These are the cases that may have a sinus thrombosis or go on to abscess formation in the cranial cavity.

In treating the acute infectious diseases the ear should be examined and at the first indication of any change in the drum membrane, or if the land marks are clouded, prompt treatment should be instituted. Care should be exercised in the use of all cleansing solutions in the nose and throat. It is an easy matter to force the cleansing solution through the Eustachian tube into the middle ear, and by so doing some bacteria may be carried into the middle ear cavity with the fluid. This is especially true in young children, owing to the Eustachian tube being shorter and broader as well as more patent, in young childhood than in adult life. It is far better not to spray the nose or throat or use swabs or gargles in a child that strongly resists, for in forcing him to take the treatment much harm may be done to the Eustachian tube and middle ear by forcing a part of the solution used in the treatment, or carrying bacteria into the middle ear cavity with the solution.

SYMPTOMS.

Pain is one of the first symptoms that the patient complains of. This pain is deep seated, boring in character and worse at night. This is especially true on retiring. Resuming the recumbent posture seems to increase the

intensity of the pain. The throbbing is in unison with the radial pulse, and the suffering is increased with every act of swallowing, coughing, blowing the nose, sneezing or jarring of the body. Usually the pain is preceded with a chill and there may be a slight rise of temperature and headache, but these symptoms may be overlooked in those cases of otitis secondary to the acute infectious diseases, as they are symptoms similar to those found during the acute infectious diseases.

The first symptom that may point to the middle ear infection may be the severe earache, or in those cases with a virulent infection, the drum membrane may rupture in a few hours and the discharge associated with pain, will call the attention to the seat of the trouble. In these cases, with an early perforation of the drum membrane, should the pain return in a few hours or in the course of a day or two, this return of pain is a sure indication that the opening in the drum membrane is too small and not affording free drainage. Should the acute otitis be of a catarrhal type, the exudate may find its way out through the Eustachian tube. More often however, the pain is so annoying and the prostration so great, that relief is sought and the patient may be relieved at once by a free incision through the drum membrane. This incision not only relieves the suffering of the individual, but prevents the binding down of the ossicles by a free drainage of the middle ear cavity.

All individuals suffering with any of the acute infectious diseases are likely to have an involvement of the middle ear and the drum membrane should be examined daily by the aid of the head mirror and reflected light, and any abnormality in the drum should arouse the suspicion of the attending physician. The first symptom seen on inspection of the drum membrane, is a reddening of the drum head at its junction with the external canal, a little later the short process and the handle of the malleus becomes red, the light reflex disappears and the greater part of the membrane tympanic is red, thickened and all of the land marks disappear. The inflammatory condition may stop at this stage, but more often the process goes on to a serous, suppurative state, then fluid is seen behind the drum membrane, or if there is much secretion within the middle ear cavity a marked bulging may be found in any quadrant of the drum membrane. Usually it is the superior quadrant that bulge, but the location of the bulging depends on a number of conditions of the middle ear. For instance, if there has been adhesions within the middle ear involving the ossicles, the small amount of pus may be walled off, as it were, causing a bulging in any of the quadrants. Again, this condi-

tion may exist with fluid in the middle ear cavity and the pocket not noticed until a free incision had been made and all of the cavity drained, excepting the portion walled off by former adhesions.

The posture of the patient also influences the position of the fluid, and it is well to have the patient in an upright position in examining the ear, for many times the fluid will be seen with the patient in this position, whereas if the examination is made in the recumbent posture the bulging may be seen in a different quadrant or overlooked entirely.

The drum membrane should not be permitted to rupture, and in fact, if a close watch is kept on the ear during the treatment of those conditions known to be followed with middle ear complications, a clean incision will be made, the drum head will be preserved and there will be far less cases of the chronic type of otitis to treat. A free incision heals readily, in fact, incision through the drum membrane in many instances repairs itself many times before the middle ear cavity has been emptied of all the secretion that forms within the cavity.

SEQUELA.

Impairment of hearing to a certain extent, always follows an involvement of the middle ear, even in those conditions classed as a simple catarrhal otitis due to the adhesions following the partial absorption of the exudate and the binding of the ossicles to each other or to the walls of the tympanic cavity. The drum head may also be involved by being drawn in and adhering to the tympanic walls, causing a progressive deafness with a severe tinnitus which becomes very distressing to the individual. Permanent deafness is a frequent complication following measles, scarlet fever and diphtheria. In fifty per cent. of all cases of measles in young childhood, there is some involvement of the middle ear and as this disease is considered of no importance from the standpoint of the laity, it behooves us as physicians, not only to educate the parents to consider measles as one of the most treacherous diseases of young childhood, but we, as medical men, should be prepared to examine the middle ear of all children afflicted with this disease and be able to give the throat and ear the prompt and early treatment required in this condition. Many cases of middle ear involvement following the acute infectious diseases not only leave a complete destruction of the drum head but a destruction of the ossicles as well. Some of these cases may have partial hearing, whereas others are doomed to go through life unable to hear a general conversation, with a discharging ear on one or both sides. The individual with a chronic otitis is an impaired risk so considered by all life insurance companies.

In fact, he is in constant danger of the necrosis extending to some vital point, causing either a brain abscess or a meningitis that may be the cause of his demise at any time. Should he be fortunate enough to not have a cranial complication, he will go through life unable to hear, his earning capacity will be lowered and in the course of time his voice becomes impaired and the individual practically becomes a mute.

In practically all cases of acute suppurative otitis media, there is an involvement of the mastoid antrum with an early diagnosis and a free incision and good drainage established, the mastoid cells may escape involvement. In those cases, with a streptococcus infection, usually the mastoid antrum and cells as well, are involved and it is these cases in which the destruction of bone is very rapid; the lateral sinus or middle fossa may be denuded in a short time complicating the mastoid involvement and endangering the life of the patient. In all infections of the middle ear following the lagrippe, mastoid involvement is frequent and as the infection is virulent, the drum membrane should be incised early, and if the mastoid becomes involved, the earlier the cells are obliterated, the better is the chance of the patient to survive the operation. Death may result early in the disease due to meningitis, sinus thrombosis, septicaemia or a brain abscess. The meninges may be involved by the infection through the labyrinth, the tegmen, nutri or tympanum or through one of the open sutures of the temporal bone in infants and young children.

PROGNOSIS.

The prognosis in the acute suppurative type of otitis media is good, if the proper treatment is commenced early; delay may be followed with changes in the structures of the middle ear that will interfere materially with the patient's hearing. Individuals with syphilis or tuberculosis do not respond to treatment, and the prognosis as to a complete recovery should be guarded. Those individuals with obstructions of the upper air tract may respond promptly to treatment, and have a relapse due to the condition of the epipharynx and fauces.

The duration of the catarrhal type of middle ear trouble is usually from one to six weeks, but in some cases, where treatment is commenced early, it may be aborted in one or two days. The pain will be the first symptom to disappear. The drum head will return to its normal color and in a few days the tinnitus may subside, but in many cases this condition continues for several weeks, or it may remain indefinitely, becoming a chronic condition.

The prognosis in the acute suppurative type depends upon the early recognition of the trouble and the treatment instituted. Should

the drum membrane be allowed to rupture, and the condition go on without treatment for a few days, irreparable damage may have been done. In some of these cases, practically all of the drum head is destroyed and on looking into the external ear, the middle ear is seen through the speculum. Fortunately, some of these cases have a fair amount of hearing, but this is the exception, and not the rule.

The necrosis of the ossicles and the adhesive processes following the acute suppurative type, always makes the prognosis doubtful, and in all of these cases that have been discharging six weeks or longer, should be considered as chronic and treated as such. These are the cases that usually have a necrosis of the ossicles and the discharge continues until all dead bone is removed, whether it be the bones in the middle ear or the mastoid cells.

TREATMENT.

It is the pain in middle ear conditions, that prompts the patient to seek relief from the physician, and in many of these cases the advice of the medical man is not asked for nor followed if given in reference to the treating of the cause of the middle ear trouble. Frequently, as soon as the pain disappears, the patient remains away from the doctor, and either has a return of the trouble or the acute tubal catarrh becomes the chronic form with a progressive deafness that in a few years renders the individual unable to hear a general conversation.

Pain being the most prominent symptom in middle ear involvement, it is this symptom that the physician is asked to relieve, and there is nothing that can take the place of opium, or some of its derivatives, and any solution that may be used in the external meatus, will practically be useless as far as the relief of pain is concerned without a narcotic being used in conjunction with the external treatment. The drum head will not be penetrated by any solution used in the external ear, nor will any solution so used be absorbed by the drum membrane, and all solutions used externally exert their influence either by the heat, as most solutions are used as hot as they can be borne, or by their hygroscopic properties on the surrounding tissue. Dry heat applied to the face and external ear, has a tendency to relieve the pain; a solution of glycerine and carbolic acid 12 per cent. dropped in the ear as warm as can be borne, affords some relief. Another favorite preparation is equal parts of crystals, carbolic acid, cocain and menthol, allowing the crystals to liquify and then instill a few drops into the meatus. Glycerine may be used instead of the menthol. The fumes of chloroform may be used—a small piece of cotton is put in the

bowl of a pipe and the stem inserted into the external meatus, and the physician blowing the fumes through the stem of the pipe by covering the bowl with his lips. Leaches may be used over the tragus, or over the mastoid process, and there is nothing that gives quicker or better results in the treatment of these cases, than the use of the leach. A blister should never be used, for by so doing the injured integument over the mastoid process may interfere with the diagnosis of an involvement of the mastoid cells.

Inflation in the early stage of an acute otitis is harmful and if used in the second stage, should be done by the physician and all antiseptic precautions taken. The catheter should be used if possible, and only under the most favorable circumstances should the Politzer method be used, and never should the bag be given into the hands of the patient for his own treatment. Valsalva method of inflation is mentioned only to be condemned, and is a dangerous remedy to put in the hands of a patient. Internal treatment in these cases cannot be dispensed with. The coal tar preparations have their uses. Calomel in large doses followed with a saline, help to deplete the fluid in the middle ear cavity. Local treatment to the nose and throat should not be neglected. Gargles given flat on the back or with the head thrown back and the tongue out, are useful in the treatment. The solution used as a gargle should be as hot as the patient can stand it, cocain applied to the mucous membrane of the Eustachian tube promotes drainage and relieves the tension within the middle ear cavity. The drum head should be examined frequently and as soon as fluid is found within the middle ear cavity, a free incision should be made. Before any incision is made, the external canal must be rendered aseptic by the use of bichloride solution, alcohol or by the use of iodine well rubbed into the skin and hair follicles. The incision should be made over the point where the greatest amount of bulging exists and should be free enough to promote drainage. As no remedy is known that will so deaden the drum membrane that an incision can be made through the drum head without pain, it is well to always consider the use of a general anesthetic in these cases. Especially should this be done if the patient is nervous or hard to control.

After the drum head is incised, nothing should be inserted in the external canal in the way of drainage. A small piece of cotton may be placed lightly in the canal to catch the discharge and replace with a clean piece as soon as soiled.

In the acute catarrhal cases, douches in the ear will do no harm and may convert an acute catarrhal otitis into one of the purulent type.

It is far better to wipe out the middle ear cavity with a piece of sterile cotton on a probe, and by being careful of your asepsis, the discharge soon ceases and the drum membrane is rapidly repaired.

In the purulent type, free drainage must be secured and the ear cavity kept perfectly clean, either by use of a cotton wound probe or by the use of warm alkaline solution and then the ear mopped out until the cavity is dry. Care must be used in the washing of the ear, for any force may carry the infection to the inner ear, or to the mastoid cells. Peroxide of hydrogen must not be used in the ear, if the drum membrane is not intact, for if this drug is used, and there is a perforation, the infection is likely to be carried to the antrum and mastoid cells or be forced through the oval or round window into the inner ear.

Powder in some cases is of use, but should the perforation be small, the powder will block the opening through the drum membrane and prevent free drainage.

Alcohol, boracic acid and distilled water, is one of the best remedies to use in the acute cases. The mixture is instilled into the ear luke warm and the patient is kept in the recumbent posture with the ear uppermost until the alcohol evaporates and leaves the boracic acid distributed over the diseased ear.

In those cases, with any obstruction in the throat or naso pharynx, the ear seldom ceases discharging and remains well until the obstruction has been removed, and it is well to remember in these cases, not to make a favorable prognosis until all likelihood of a recurrence from diseased lymphoid tissue has been removed. Frequently these ears may stop discharging for a short time but as soon as a fresh cold is contracted the discharge again appears.

A GENERAL PRACTITIONER'S LABORATORY.*

By L. A. TATE, Louisville.

Good routine clinical analysis of the practical sort has become as essential to the successful practice of medicine as physical diagnosis and in many instances is of vastly more service. The use of instruments of precision has taken the place of cruder methods in every branch of science and in medicine the day of snap-shot diagnosis has past and gone.

I shall deal in this paper with the workings of practical laboratory such as any busy practitioner could operate with very little expenditure of time and very little thought after he has established a routine.

First and last I wish to dispel the idea,

which I have heard expressed, that it requires a skilled and thoroughly trained chemist and microscopist to do this work successfully. It is a mistake; any doctor who is so disposed can take a good microscope, centrifuge, slides and cover glasses, an alcohol lamp, test tubes, glass tubing, red and blue litmus paper, urinometer, filter paper and stand, burette, 2 porcelain dishes, 2 graduated beakers, and with the aid of a short list of stains and reagents purchased ready prepared through the druggist, can make all of the most practical examinations of the blood, stomach contents, feces, sputum, milk, urethral and other discharges and urine.

In regard to blood examination it is my opinion that the microscopic diagnosis of malaria and the estimation of hemoglobin by the Talquist method are the only procedures available for the general practitioner. The differential blood count is easy but it requires a mechanical stage and a rather exact knowledge of the morphology and staining peculiarities of the various cells. I would not advise the red and white cell counts for the practitioner because of the time it takes and the rather expensive apparatus necessary. But the estimation of hemoglobin by comparing a drop of the patient's blood collected on a slip of bilulous paper (with a graduated color scale) is a simple and often useful procedure. And the diagnosis of malaria microscopically is easy, practically and almost absolutely without fallacy. It can be done two ways, namely the fresh drop method and the stained smear of which the last method is the more generally satisfactory. The drop is taken from the finger or ear lobe and a thin film obtained by placing a second cover glass over the one on which the drop was collected and then the two slid apart; this is then stained with Wright's stain and examined under the oil immersion lens. The parasites is easily seen even by the most inexperienced. Under the heading of blood examinations the Widal test might be mentioned. Park Davis & Co., sell an outfit known as an agglutometer with which a practical Widal test can be made without the aid of a microscope. The result with this instrument is very satisfactory and is worthy of commendation.

A comprehensive study of the stomach contents will not be attempted here. There are several valuable tests, none of which require any especial skill or knowledge of chemistry, among which might be mentioned the test for lactic acid, the presence of which in the stomach washings is fairly diagnostic of cancer; the determination of the total acidity, free hydrochloric acid and of the peptic digestion, all of the service differentiating the various dyspepsias. The motor power of the stomach

*Read before the Christian County Medical Society.

is an important factor in digestion and the estimation of this function is one of the most valuable of the stomach examinations; the usual method is to wash out the stomach six hours after an ordinary meal and examine the food in the washings the presence of which would mean a deficiency of motor power and the length of time after a meal that food is still present in the stomach indicates the degree of this deficiency. Another method is to administer salol by the mouth and examine the urine every one-half to one hour for salicylic acid, which should normally appear in from 60 to 75 minutes. It is detected by adding a few drops of ferric chloride solution to the urine which gives a brownish or violet color in the presence of salicylic acid.

The estimation of the absorptive power and of the capacity of the stomach are easy to make and are helpful in diagnosis.

The examination of the feces under the microscope will sometimes make clear the diagnosis in an otherwise obscure condition, by the finding and recognition of vegetable or animal parasites.

The importance of breast milk examinations appeals to every doctor because of the problems of infant feeding involved. A good practical examination can be made with no other instruments than a cream gauge and a lactometer, or even an ordinary urinometer may be used instead of the lactometer if the quantity of the milk collected is sufficient. By the cream gauge we estimate the amount of fat and by the ratio between amount of fat and specific gravity of the specimen we are able to compute approximately the proteid content. The other constituents, sugar and salt, are nearly constant and are of minor importance.

Sputum examination, especially as an aid in the diagnosis of phthisis should be a routine practice with every doctor. A cheesy mass from the sputum cup should be teased out on a slide and stained with carbol-fuchsin. The rod-like bacteria of Koch takes the bright red acid stain and are plainly visible under the oil immersion. Positive findings are, of course, diagnostic but negative results are of no value. Hence the necessity of repeated examinations. The examinations of urethral discharge for the gonococcus is valuable from the prognostic standpoint as well as the diagnostic. The Gram's method of staining should be employed, by which method gonococci are decolorized and take the Bismark brown-counter stain while the other bacteria retain the violet color.

Much could be said on the subject of urinalysis but I shall content myself here with a very brief outline of the routine methods which have given satisfaction. When convenient a portion of the 24-hour specimen

passed into a clean vessel, should be used for examination, but when this method for any reason is not available, collected specimen from one micturition, preferably passed in the P. M., about three or four o'clock. The specific gravity of the specimen should first be taken and while doing this the color and odor may be noted; determine the reaction with red or blue litmus paper; then test for albumin by heat and nitric acid controlled by Heller's nitric acid ring or contact test. Use Hanes' method for testing for sugar. The test for urea, bile or indican may then be made if the symptoms indicate the advisability. Also, if you haven't the microscope, the presence of pus may be determined by adding a few drops of potassium hydrate to the specimen, which will throw down a rosy precipitate when test is positive.

Blood will give a robin's egg blue juncture line when the suspected urine (or other fluids) is made to underlie the mixture of 4 or 5 c.c. tr. guaiacum and one-half as much hydrogen peroxide. There are other chemical tests of urine but these outlined are the most important.

The microscopic examination of urinary sediment is exceedingly useful. A good handpower centrifugal machine is a necessity here. The presence of many things may be demonstrated by this means, among the most important of which may be mentioned blood, pus, casts, epithelial cells, bacteria, and various crystals.

Urinalysis is especially valuable in the differentiation of the various forms of nephritis; so it might be well to insert here a brief summary of the typical urinary findings of the most common forms, namely, acute parenchymatous, chronic parenchymatous and chronic interstitial nephritis. In acute parenchymatous nephritis the urine is dark in color, and smoky, (due to be) usually acid in reaction, light in specific gravity, 1025 to 1030, and highly albuminous. There is a large amount of red-brown sediment which, when subjected to microscopical examination, is found to be made up of large epithelial casts, blood casts, few granular casts and some hyaline and half and half casts; clumps and layers of round kidney cells with their distinct nuclei are seen. The number of casts effect the prognosis, the more numerous they are the worse the prognosis.

In chronic parenchymatous there are two stages, that of the large white kidney and that of the small white or secondarily contracted kidney. In the first mentioned stage the urine is pale and low in specific gravity, except very early, when the specific gravity may be higher, but it is soon lowered, coincident with an increase in quantity. Albumin is considerable but not as much as in acute

parenchymatous. There is a white deposit which is made up of large hyaline, granular, and sometimes, epithelial casts, which last are of grave prognostic significance. Urea is always diminished, usually running around 1 per cent.; when it falls to five per cent. or lower, there is imminent danger from uremia.

As the kidney becomes secondarily contracted, (if the case progresses this far), and the second stage sets in, there is an increase in quantity of urine indicated by more frequent micturition, specific gravity goes still lower, albumin is diminished and the sediment becomes much less in amount. The majority of the casts are small but there will still be some large ones in the specimen. The casts are mostly finely or coarsely granular, and sometimes late in the disease fatty and waxy, which means that the end is not far off.

Chronic interstitial nephritis is slow in its course and is associated with high arterial tension and diseased blood vessels. Urine increased in amount and night micturition is an early sign. Albumin is trifling and transient; specific gravity 1015 to 1018; urea slightly diminished; casts are small, sometimes very small, are hyaline and granular and few in number. Oil droplets are frequently seen scattered through the urine of this condition and are usually associated with grave pathology.

I have endeavored to eliminate tedious detail with a view of bringing out the actual, everyday value of a small laboratory for the practical work of the general practitioner. The apparatus is not expensive and with the aid of epitomized books on the subject, for ready reference, satisfactory chemical and microscopical examinations can be made even by the most inexperienced. It is not necessary to carry the technique of all the tests in mind, but keep the little book at hand and know it well enough to be able to turn to any test and perform it by the rules there set forth.

Epilepsy and Pregnancy.—In women with epilepsy in whom pregnancy apparently causes the convulsions to become more frequent or more severe, Miller says one should always consider the necessity of terminating the pregnancy. In cases of pregnancy in epileptic women, one should watch with extreme care for indications of toxemia or the premonitory signs of eclampsia and should put an end to pregnancy at the appearance of symptoms of much less gravity than would indicate this procedure in women who are not the subjects of disease. He cites one case.

CAESAREAN SECTION.*

By A. H. BARKLEY, Lexington.

There is perhaps no operation which has behind it the history that Caesarean section has. Many erroneous ideas and misstatements have been handed down and accepted as true without question. The statement that many persons of prominence both in ancient and recent times have been born in this manner, is frequently met with; the fact, however, remains that while a few historical personages were so born, many were not. The very early writers on medicine are silent on this subject; thus no mention of it occurs in the works either genuine or false, of Hippocrates, Celsus, or Paulus Aegineus. Pliny tells us that Scipio Africanus, the vanquisher of Hannibal, was brought into the world by this operation.

It is generally believed that Julius Caesar was born in this manner, and that the operation thus took its name. If this is a fact, which I doubt, his mother survived the operation, as she died while he was prosecuting the war with France. Indeed, there is nothing in history to warrant the belief that he was born in this unusual manner. It perhaps was due to the fact that the ancients thought it necessary to invest the birth of so great a man as Julius Caesar with extraordinary circumstances.

Shakespeare has not overlooked the advantage he might derive from the incident with which tradition had invested the birth of Macduff. The last hope and frantic desperation of Macbeth built upon the apparition's prophecy,

"I bear a charmed life which must not yield
To one of woman's kind"
suddenly forsakes him, when Macduff declares to him the manner in which he was introduced into the world.

"Despair thy charm
And let the angel whom thou still hast served
Tell thee Macduff was from his mother's womb
Untimely ripped."

There is no question but that the Jews were acquainted with this operation and practiced it with an occasional success. It is said that Numa, the second King of Rome, caused to be enacted such a law as would forbid the burning or burial of any woman dying in childbirth until the child had been removed from the womb by incision.

The earliest account in medical works of this operation will be found in the writings of Guy de Cauliac in 1363. He speaks of it only as an operation to be performed after

*Delivered before the Second and Third Class at American Medical College, St. Louis, Mo., March, 1912.

death. Pare speaks of it as an operation only for the dead mother, and frowns upon the idea of its ever becoming an ante-mortem operation. The first case that was ever intelligently described was that of a sow-gelder's wife in 1500. This heroic gentleman operated on his own wife, saving both mother and child. There had been no attempt up to this time by any one to put the operation upon a scientific basis, and it remained for Roussel in 1582 to collect what cases he could and draw such conclusions as to finally put the operation on a sound footing. Various operators lay claim to priority in the performance of Caesarean section, as Dixon (*Am. Jour. Med. Science*, Vol. 124, 1902) states the first case was done in Switzerland in 1498, while the first physician to operate was Trautman of Wittenberg in 1610. Both of these operations were done for deformed pelvis.

In all the ancient works that treat on this subject, they universally condemn its performance until after the death of the mother. It is indeed surprising that the operation was performed on the dead body at all, knowing as we do what profound respect the ancients held for their dead, as in those days operations were not performed with the same free hand as they are to-day. However, be it as it may, they were performed upon the dead mother, and done successfully so far as the child was concerned. There are many cases on record which are short of miraculous. Cesseur in 1901 (*Munich Med. Woch.* No. 11) reports a case in which he operated ten minutes after death from eclampsia, saving the child. Plinger reports a case in the Dresden clinics in which a mother was operated upon nineteen minutes after death, saving the child. He also cites a case in his own practice wherein he succeeded in saving the child twenty-five minutes after the mother's death. I mention these cases partly because of their rarity, and also on account of the possibilities the operation offers to the child.

I presume at the present day it is needless to admonish the profession as to the propriety of operating when possible before death as the foetal mortality runs something like 95 per cent. Sir Ould in 1742 was the first man of any prominence to advise operating at the beginning of labor in those cases when delivery of a living child was impossible due to any mechanical obstruction along the parturient canal. It is needless to say that the opposition at so early a date was very great; but being a man who had the courage of his convictions, he thoroughly demonstrated to the satisfaction of all that it was a logical procedure in well selected cases, and it was not long before he had many converts among whom were such men as Burton, Smellie and others equally prominent. They readily foresaw

what might be gained by performing the operation before the patient was moribund, and gave an impetus to the operation which it has since sustained. Perhaps no operation has been so much improved by asepsis and perfect technic as the one under discussion. The profession has grasped the situation and has readily taken advantage of the fact that early operation is the only one to be considered in obstetric surgery. As has been said, it was formerly performed on dead or moribund patients, and the mortality following the operation was as large, if not more so than the condition which it was undertaken to relieve. This caused many excellent surgeons in the pre-antiseptic era to hesitate to perform it.

Fritsch of Bon in speaking of the antiseptics in Caesarean section says, "The benefits of antiseptics in Caesarean section have been remarkable. Before the most favorable statistics showed the mortality of 50 per cent. compared with 5 per cent now due to the operation in the hands of Leopold and others, and indications are so enfranchised that the perforation of a living child is almost considered a crime.

INDICATIONS.

This operation is demanded in any case where there is such disproportion between the parturient canal and the child or vice versa, or where there exists an obstruction due to a growth either malignant or benign, either of the mother or child, that delivery *per vias naturales* is impossible.

There are other conditions arising on the part of the mother that may demand operative interference, and since Caesarean section has within the past few years gained such favor, it now infrequently happens that such contingencies are successfully met by the judicious employment of the operation in question. I refer to placenta previa and eclampsia.

Although the conditions have been broadly stated above, it is well to mention a few of the most frequent conditions that demand its performance:

- 1st. Contracted and deformed pelvis.
- 2nd. Tumors either of the child or the mother.
- 3rd. Eclampsia.
- 4th. Placenta previa.
- 5th. Vaginal deformities.

In *contracted pelvis* it is not always easy or possible to say that a given case will have to go through the ordeal of an operation. Thus the decision at the beginning of labor in a primipara with a moderate degree of contraction, between the Caesarean section and intra-pelvic delivery is intrinsically so difficult that it is almost impossible to decide, and none but the most experienced should attempt it. We should not decide alone on external

measurements, as there are other conditions that may help out materially. The height of the anterior superior spines above the pubes, length of the sacrum and symphysis, also, the inclination of the sacrum and plevic brim while the patient is standing. A careful vaginal examination with reference to the walls of the pelvis should be made; in fact, it is very necessary to keep a close watch in all cases of labor that you are called to attend, and more especially those cases where from previous history one may anticipate trouble.

It has been said by one of the most expert men in this country, "When a woman with a moderate contraction of the pelvis has lost one child, she should be in the next labor prepared for Caesarean section, and delivered by it unless the course of labor shows some changed condition; e. g., a small child, or a more favorable position, in which case a forceps delivery is likely to be easy."

In a pelvis with 2 1-2 inches or less, it is almost a certainty that the child will succumb. In a case where the contraction is 2 3-4 inches, it is possible to deliver a living child, though the probabilities are remote that it will continue to live—due to long labors as a rule in these cases. One is justified in performing Caesarean section when the conjugate is even above 2 3-4 inches, where the head is relatively enlarged.

In deformed pelvis, those that are likely to give rise to trouble and demand operation are the *uniformly contracted pelvis*, *obliquely contracted pelvis*, and a *flat rachitic pelvis*, all having a conjugate vera of less than 6 1-2 c.m.

It does not follow in every case of deformed pelvis that an operation will be necessary. This is true in contracted pelvis, as in this latter condition the diameter may be contracted in such a manner as to allow a child with a small head to pass safely.

Tumors either of the mother or child may preclude the possibility of delivery. Tumors may be found in the uterus, located either in its body or in the cervix. Fibroid tumors of some size may, if situated in or near the fundus, permit of safe delivery, but if they involve the lower segment or are pedunculated, they almost without exception cause trouble. The same holds good for tumors of the ovaries; as, in one of my cases, a large cystic tumor of the right ovary necessitated Caesarean section. Bony tumors of the pelvis are not so common; however, they may be present, and of such size as to materially interfere with the progress of labor; as, in another case which I operated upon, by Caesarean section, a large bony tumor was found at the sacro-iliac junction near the size of one's fist.

Malignant conditions of the body of the uterus are best treated by section. Some op-

erators much prefer vaginal Caesarean section in cases suffering from malignant condition of the cervix, claiming that they have better access to the parts involved.

Tumors involving the child are relatively rare; however, one condition does exist and is not infrequently met, though not properly classed under tumors; that is, hydrocephalus. A child with a large hydrocephalic head calls for operative interference as delivery in the natural way is impossible.

Eclampsia. There is still some doubt as to the propriety of this operation in eclamptic cases. The mortality is still too high in these cases regardless of the method employed; but upon a close analysis of statistics of a large number of cases treated by Caesarean section, it will be found that in the majority of instances only the worse cases come to operation, which is not a fair test of the possibilities of the operation, and under such circumstances it was found that the foetal mortality was reduced somewhat while that of the mother was slightly raised.

Now if these cases were operated upon at the outset instead of making the operation one of last resort when the mother has had every chance for infection, the mortality to both mother and child would be materially lowered. It is the delay and infection that kills the patient, and not the operation when quickly and skillfully performed. It should be the operation of choice when in the judgment of the operator it offers the best chance of saving both mother and child.

Placenta Previa. Up to a few years ago the mortality where version or Caesarean section was employed were about the same; but so much has been written of late about early operation that Caesarean section has become more popular, and in well selected cases it has very materially reduced both maternal and foetal mortality. This is especially true in central implantation with a hard and unyielding cervix.

The last indication, *vaginal deformities*, are not often encountered. There may be deformity resulting from bands, scars, etc., or the vagina may be unduly small. Any of the above conditions are of sufficient importance to indicate the performance of Caesarean section.

TIME FOR AND CHOICE OF OPERATION.

It was formerly considered time for Caesarean section when all other methods had failed to accomplish delivery; but the mortality was so high that it became apparent that the attending physician should know when the patient was able to deliver herself, and be prepared in advance to apply proper measures for the successful delivery in a given case. The mortality to the mother in version and high forceps are about the same as early

Caesarean section; the foetal mortality is much higher in version or high forceps, amounting to not less than thirty per cent. when done for mechanical obstruction.

While it is very desirable to employ an operation that gives the lowest mortality, it is also desirable to employ the operation that will leave the woman in the best condition and free from morbidities.

This is what can be claimed for Caesarean section. Every one of you will be called upon some time during your professional life to repair the damage done during delivery by version or high forceps, and sometimes you will be successful and sometimes not. These injuries range from rupture of the uterus to laceration in the pelvic floor and incontinence of urine and feces, or a permanently damaged ovary or tube. All these weigh heavily against such procedures in the class of cases under consideration.

I think it can be safely said that while other obstetric operations are sometimes employed, Caesarean section offers better chances to the mother and child, with the minimum amount of morbidity.

Again referring to the time of operation, it is highly necessary to appreciate the fact that the earlier, the better, as it is in those cases that are operated upon before infection has taken place and the soft parts subjected to traumatism that ideal results are obtained. The operation should be done before the membranes have ruptured if possible, as this lessens the possibility of infection. Reynolds, of Boston, in a very extended research upon this point, clearly showed that when Caesarean section was performed early, say before labor set in, the mortality in competent hands is about one per cent. He cites eighty-two cases operated upon before labor had begun, with only one death and says this death could not be attributed to the operation but to a break in the technic; also, one hundred and fifty-eight cases operated upon after the advent of labor, none exceeding six hours, with a mortality of four per cent.; also forty-nine cases that were operated upon very late, with a mortality of twelve per cent. He includes in the last class of cases those who had pains and where the cervix was sufficiently dilated, but says that in badly neglected cases the mortality is much higher.

Caesarean section as compared with symphysiotomy and craniotomy in the light of present statistics and under similar circumstances are as follows:

	Maternal Mortality Per Ct.	Foetal Mortality. Per Ct.
(1) Caesarean Section....	1	1
(2) Symphysiotomy.....	11	15
(3) Craniotomy.....	9	100

THE DOCTOR AS AN EXPERT WITNESS.*

By HON. HERBERT L. WAGGENER, Bardwell.

It affords me great pleasure to have the honor of reading a paper before you at your meeting as I feel that it should be considered an honor to be granted so much of your valuable time to so do, as I realize the great importance of these meetings and how much they mean to humanity in its great strife in combatting the diseases that ravage our country; that at these meetings are brought to light methods by which seeming unsurmountable obstacles may be brushed aside and life meted out to the stricken ones and happiness reign where sorrow and death sought to hold sway in its supremacy. And it is the fruit that is borne from these meetings, gentlemen, that has caused humanity to recognize your profession as the most important in the world; that it is your hands that hold the life-line that has saved countless thousands from being cast into the sea of eternity from which no man may return.

But, gentlemen, it is not always by the use of surgical or medical means or aid that you may save or take a life; there is still another means, if used courageously and honorably, place it in your power to condemn a contemptible murderer or save some innocent man from filling a felon's grave. That, gentlemen, is known as the legal term of expert testimony. Whenever a life has been taken by some unnatural means, it is to the practical experienced physician that the executives of the law must turn for light and solution as to by what means the life was taken, whether by another or by the hands of the deceased himself, and on his decision hangs the life or death in all probability of an accused man.

To properly impart the knowledge gleaned by an examination of a subject, all physicians should know what and how to tell the jury on an oral or written examination by an attorney his conclusions. These conclusions are arrived at in two ways:

1st. By an actual examination of the subject itself.

2nd. By hearing other witnesses testify as to the conditions surrounding the subject and draw therefrom his conclusions.

These conclusions are then accepted by the court and called proof. The physician who is summoned to testify should also know what would be considered proof; hence, what is proof?

Proof is logically defined as the sufficient reason for assenting to a proposition as true, proof comprehends all the grounds on which rests assent to a specific proposition. Proof

*Read before the Carlisle County Medical Society.

should not be tainted with moral conclusions: For example: You may have heard that A killed B. You know that A is a bad man, B has died an unnatural or violent death. You might morally conclude that A did kill B, and this moral conclusion might serve to prejudice you on an examination of the body to ascertain in the manner in which B came to be killed, whether by his own hand or the hand of another. Hence it is essential for an examining physician to lay aside all moral conclusions and keep them from his evidence and examination. Therefore as the evidence of a physician is so essential in cases requiring their conclusions from scientific examination that it is necessary for such physician to know about what medico-legal questions may be asked and what to look for in his examination of the subject, hence so as to illustrate this proposition I will take for example the examination of the bodies of persons found dead, who apparently did not die natural deaths. Under this division arise a great many interesting subjects of inquiry. These as far as possible I shall present in a natural order.

1st. What was the weapon with which the wound was inflicted?

It may become important for many reasons to ascertain the kind of weapon by which the wound was inflicted. It may be a means of identifying the murderer. It may serve to qualify in some measure, the nature of the action, rendering it murderous or not, according to the weapon used. It is possible to infer, to some extent, how the injury has been inflicted from the superficial or deep seated character of the contusion. If a stone is struck smartly with a small hammer the blow is practically expended on the surface, while the interior remains uninjured. But if the same is struck a slow, heavy blow with a ponderous hammer the force penetrates the interior and shivers its center, producing little or no injury of the surface. This principle applied to contusions on the human body justifies the general inference that wounds of a superficial character have been inflicted by the small strike of a comparatively light body, while those which are deeper seated have been occasioned by heavy blows from a more ponderous weapon. It is upon this principle that there are many instances on record where death has resulted from a violent contusion without leaving any external mark of injury.

2nd. The second general question that arises is: Was the wound self-inflicted, or accidental, or the act of another?

The settlement of this question must depend much upon the peculiar circumstances of each individual case. It may be important to attend. First to the situation in which the body is found.

A body found in a room locked on the inside, the throat cut, and the instrument of death near at hand, would not only justify but would require the inference that the act was suicidal. So also it would be about equally clear, if a body found divested of life by a similar wound in a room accessible to others, the weapon of death being removed, that it was neither suicidal nor accidental, but the act of another.

Second. The nature and situation of the wound or injury, may indicate the manner in which this question should be settled. So far as the nature of it is concerned, it may be assumed that contusions are seldom self-inflicted but may result either from accident or homicide? They may, it is true, be inflicted by throwing oneself over a precipice or out of a window, but in such cases the cause of death is very apparent. It is very important to examine the situation of the contusion. It may be found on a part of the body which could not have been injured by an accidental fall, as on the inner side of the legs or arms. Those very severe contusions or lacerations that must necessarily have been produced by a ponderous weapon, such as an ax or hammer, have, in all probability been inflicted by another for a murderous purpose. The direction of the wound will sometimes afford an indication whether it be suicidal, accidental or homicidal. In suicidal wounds effecting the throat the direction of the cut is the most commonly observed to be from left to right, either transversely or obliquely from above downwards. In suicidal stabs and punctured wounds the direction is on the supposition that the individual was right handed which is not always the case. One good method that has been recommended is to place the weapon in the hand of the deceased, and then by moving the hand and arm ascertain whether the wound could have possibly been inflicted by him or directed to a vital spot either to the brain or the heart. Another important thing to notice is that they possess the character of wounds inflicted near the body, such as blackened and burned skin, the wide lacerated wound, the discharged pistol near the hand, often blackened by its discharge and some times within its grasp. An interesting case illustrating this last remark occurred in France in 1895. The body of the deceased was found sitting in a chair by the side of the bed, his elbow resting on the bolster, and his right hand lying over the right thigh and grasping a pistol which appeared to have been recently discharged. The death was evidently caused by a severe gun-shot wound of the head. The son slept in the same room with the deceased and he was accused of having murdered his parent, and then of having placed the pistol in his hand to give the whole as

appearance of suicide. There were some moral circumstances against the son; but the fact principally relied upon was that when the hand with the pistol within it was carried to the position in which the weapon must have been held by the deceased to have committed the fatal act himself, and the hand was afterwards allowed to fall by its own weight, the pistol each time fell from the hand to the floor. The medical witness after some reflection satisfactorily accounted for the hand retaining the pistol after death, by the contractile state of the muscles continuing after death under the form of cadaverous spasm. The fact that knives and razors as well as pistols are not unfrequently grasped in the hands of the suicides is accounted for on the same principle. It is owing to the muscular spasm persisting after death and which is quite distinct from cadaverous rigidity.

The third general question proposed for discussion was: What circumstances can be gathered relative to the motive or intent of the inflictor?

It is well known that to constitute crime the moral element must enter as a constituent part into the action which it essentially qualifies. It is that which creates the wide difference between a mere injury and a wrong. The first may be caused by the kick of a horse or the blow of a maniac. The last can only proceed from a rational creature, a free moral agent. The first is limited in its effects to the mere physical nature which it injures. The last extends to and embraces the moral nature and is there felt as a wrong done to that nature. Hence the law always requires felonious intent to be clearly shown, either directly or inferentially, before conviction can be obtained for the commission of a crime. Any circumstances therefore attending its commission which will throw any light upon the question of intent, provided the fact of homicide is first established, should be seized hold of and eagerly appropriated.

We must look at the nature, situation, direction and extent of the wound. When found inflicted in a concealed part, such as a superficial observer would not be likely to notice, the inference of intent is strong. The female organs of generation have been selected as a part where a mortal wound could be inflicted, and the greatest chance of escape from its consequences afforded. The inflictors of such wounds must have entertained the impression either that they could escape entirely from the want of observation, or that the blood if observed would be attributed to flooding to which females are frequently subject, or that if the wound was actually discovered it might be accounted for by the female having accidentally injured herself by sitting down upon some sharp body. So con-

fident have they been of success that in some cases they have been the first to go for medical aid for the deceased.

In the case of Pollock, which occurred in Edinburg a wound about an inch and a quarter long was found, on separating the labia pudendi, upon the inner side of the right hympha. It was a recent clean incision admitting the point of the finger which could be inserted in four several directions, where the cellular membrane had been divided in each of these directions to the depth of two and a quarter inches. None of the larger vessels had been wounded and death had obviously resulted from hemorrhage. This as in case of a number of others that I might mention along this line clearly, by reason of the nature, situation and extent of the wound, proclaim the intent of the party. They also go to prove that where a highly vascular part is wounded by an incision death may take place in a very short time from the hemorrhage though no large vessel may have been severed.

The direction of the wound may also be an important circumstance to show the intent. This question arose in the case of Campbell who was tried for shooting a man who came to his house at night under suspicious circumstances. The defense was that the ground being rough and slippery the prisoner stumbled and both barrels of the gun had gone off by accident. This account of the matter was confirmed by tracing the direction of the shot in the body of the deceased which was found to be slanting upwards.

The fourth general question or subject of inquiry is as to the acts that indicate volition or locomotion after the infliction of mortal wounds.

It sometimes becomes an important factor to determine what possible efforts can be made by an individual after the receipt of mortal wounds. Wherever this question has arisen it has been generally in cases of injuries to the head, wounds of the heart, large blood vessels, diaphragm and bladder. Important inferences are sometimes sought to be drawn from the position in which the body is found, considered relatively with the supposed position of the murderer; without adverting to the possibility or perhaps probability of the murdered persons having changed his position after receiving the mortal wound.

As the object in this inquiry is to arrive at the maximum or utmost extent of effort which is possible after the infliction of the severest wounds it may be well briefly to mention a case or two which have occurred in which the maximum seems the clearest to have been shown. A man fell from a scaffold on the summit of his head. He was at first stunned, but on reaching the hospital dismounted

and walked upstairs with but little assistance. He died three days later, remaining perfectly rational and going to the water closet the day before his death. On examination afterwards the skull was found split from the frontal bone backwards through the sagittal suture to the foramen magnum. In both hemispheres there was a quantity of blood in a semicoagulated state, more than two ounces being found at the base of the skull.

The particulars of another extraordinary case are that a woman after being knocked down by a blow on the temple, and while down having her throat cut in such a horrible manner as to divide the trunk of the carotid artery and all of the principle branches of the external carotid with the jugulars, was nevertheless able after that to get up, leave the hotel in which the act was done, climb over a gate outside and find her way to a distance of twenty-three yards where her body was found. It will readily occur to anyone that although the power of locomotion may remain after the division of the trachea yet that all power of voice is entirely lost, and hence no calls for assistance can be made at however short a distance the murder may be perpetrated.

The fifth general question regards the length of time that has elapsed since the wound was inflicted.

The length of time that has occurred between the infliction of the wound and the time of examination is often material subject of inquiry. In the case of *Queen vs. Ramon* the prisoner was charged with maliciously cutting and wounding the prosecutrix. There was a cut on his thumb which he attempted to explain by saying that it was from an accident which occurred three weeks before. The medical testimony went to show that it could not have been done more than two or three days, which coincided with the time of the murderous assault. This, with other circumstances led to his conviction.

An incised wound, inflicted on the living body, having its different stages of progress known well by the physician, will on careful examination disclose to his practiced eye to practically an absolute certainty whether or not it was inflicted before or after death, if before, about how long before death it was inflicted, all of which is generally of the greatest importance. In the case of the *State vs. Harlan* the body of a man was found upon the right of way of a railroad company badly mutilated by a train having passed over the body. It was known that there was an extremely bad feeling existing between Harlan and the dead man. On examination by a physician it was found that death had been due to wounds inflicted prior to the time that the man was struck by the train, and that

the wounds made by the striking of the train were all made long after life had become extinct. These observations led to the conviction and ultimate confession of Harlan that he had committed the deed for which he was in due time executed.

The sixth question that we propose to discuss is: Was the wound the direct cause of death? The requirements of the law render it necessary to answer this question. In order that a person can be convicted of murder or manslaughter it is necessary that the individual should die of the injury inflicted. The law can indulge in no speculation on the subject. It requires that the death should be clearly traced to the injury and unequivocally shown to have caused the death. In a combat between two, one receives a wound which may or may not prove to be mortal and is left upon the field. Subsequently he is attacked by ruffians who strip and rob him and beat out his brains. No indictment in such a case would lie against the first assailant, because the deceased dies by the hands of others, and not of the wound inflicted in the first combat. The following case reported will serve as an illustration. In 1898 some drovers had a quarrel in Kentucky, at a wayside inn. In the course of it one of the party was wounded with a knife on the face, hand and upper part of the thorax, near the right clavicle. The injuries were found on examination to be superficial and slight. The wounded man having washed himself soon after started for his home. He was found dead the next morning bathed in blood. The left lung and pulmonary artery were found cut. The medical witness swore that this last was the cause of death, and that it must have been inflicted after the superficial wound upon the thorax which was not bloody, but surrounded by ecchymosis. The fact was, that on his way home he was robbed and murdered.

If a person of a weakly habit receives a wound of which he afterwards becomes cured; but owing to the long confinement he has been made to suffer he is taken ill of a consumption or some other malady incident to such a state of weakness and dies of this consumption or malady; no charge of homicide could be sustained as the death is directly attributable not to the wound but to the consumption or other malady which might or might not have supervened had no wound rendered the confinement necessary.

There must be a certainty as to the cause of death. If the injury sustained be one only, among many causes, that have contributed to the fatal result and the agency it has had in its production not very clearly ascertained no conviction can be obtained. Thus in the case of *William Duff* and others who broke into a house and so affrighted a poor woman in

childbed that she fell into a fever and died. The indictment was held not sustainable. Where, however, the death is traceable directly to the injury and has been clearly produced by it, no matter what may have been the situation or circumstances of the deceased, the prisoner is responsible. If the deceased were on his death bed and in the last stage of a mortal disease, still if he were shot through the head or stabbed with a lethal weapon in such a manner as to produce death sooner than it would have resulted from the disease it is murder as equally as if he had been in the vigor of health.

The last question that arises, and of the most important is: How should the medico-legal examination of wounds be conducted?

A few practical suggestions are all that can be offered under this head of inquiry: It is important, if possible, to examine a wound that presents externally, before the body has been removed from the position in which it was first found. The relations sustained by the body and the wounds, with things external to them, can then, and then only, be properly ascertained.

After examining with reference to these relations the next thing to be remarked is the kind of wound inflicted. Is it a contused wound or a lacerated, gun-shot, incised, or punctured wound? If either what was the probable instrument with which it was inflicted? Is the form and impress of the instrument defined by the contusion, as is occasionally the fact? Can anything be collected from the lacerated, incised or punctured wound in reference to the instrument of its infliction? If it be a knife or gun-shot wound are the entrance and exit holes clearly ascertainable? The existence of all foreign bodies should be carefully noted and they should be preserved. The depth of the ball may serve to indicate the distance from which it was fired, as it is known that the human body has the same resistance practically of an inch pine board. The wadding has identified the murderer. In one case half a ballad was found in it and the other half in the pocket of the accused. The bullet should be preserved to compare with the fire-arms in the possession of the accused.

If the wound be incised or punctured the quantity of hemorrhage should be ascertained with the view of determining whether it was inflicted during life. The bloodless state of the vessels is best ascertained by a reference to the organs of the abdomen and also the state of the brain.

It should be observed whether there is a clot of blood over the cut surface, and also whether any signs of living action are observable. Any appearance of inflammation, of suppuration or gangrene would be evidence of

infection during life. The length, breadth and depth of the wound should be carefully ascertained. The external or other parts of the wound should not be destroyed. As far as possible they should be kept entire. The custom observed in Paris is very admirable and worthy of imitation; that is to make a cast in plaster of all wounds in cases where bodies are found divested of life by wounding and preserve them in one particular place, called the Morgue, where they may afterwards be seen and if necessary appealed to for the purpose of discovering the murderer.

The external wound should be carefully compared with the internal injury, whether it be of blood vessels, nerves, bone or viscera. Fractures require a careful examination, to determine whether they were produced before or after death. The seat of wounds should be described by actual measurement from known points; their figure and nature also carefully noted and their direction ascertained with exactness. The latter may serve to show from what point the wound has been dealt. The most approved mode of examining injuries is if they be not situated over great cavities, to expose the successive layers of muscles in the manner of an ordinary dissection, observing carefully what injuries have been sustained by the parts successively exposed, before they are divided.

All the great cavities should be examined and every important organ in each, however, distinctly the cause of death seem to be indicated in one of them.

After examining the position of the body, things external to it should be noted; all of the objects in its vicinity, with a view to discover on what it rested or fell upon, or had been suspended from; all the marks of a struggle taking place near it; signs of the presence of a second party about the time of death or after it; weapons or other objects, the property of the deceased, or of some other individual; all remains of poisons, marks of vomiting, etc., that may be found near. To a shrewd and cautious observer, many indications of a character similar to the preceding, will present themselves.

And, so gentlemen, you see the great necessity of extreme care in preparing oneself for any and all questions that may arise in the unraveling of a mysterious death, and how very dependent the welfare of the commonwealth and the entire country in fact is upon your knowledge and its value in the upholding of justice, the punishment of the wrongdoer, and the protection of the innocent accused.

SALVARSAN IN THE TREATMENT OF SYPHILIS.

By JACOB SCHULTZ, Logmont.

Salvarsan plays a most conspicuous role in the treatment of syphilis. It has advanced the treatment to such an extent that we can render our patients safe members of society in a few days.

When this important drug was first made known to the medical profession the idea became prevalent, that syphilis could be cured with one dose, but like all new drugs erroneous claims were made by enthusiastic individuals, without any conception of conservatism.

The medical profession should use every effort possible to eradicate this idea, that seems to have become prevalent among the laity, and indeed many of the profession, that a single dose of salvarsan will cure the disease. The newspapers of the country are largely responsible for this report. They obtained data on this subject and published same in their Sunday editions, therefore the news spread broadcast, and the quacks and charlatans began to advertise a cure for syphilis with "606" in a single dose.

The idea of curing syphilis with a single treatment was a daring conception. Our old line of treatment with mercury and iodides running over a course of two to three years was the treatment par excellence before the advent of our new specific. There is no room for any doubt that salvarsan is a specific for the spirochetes of syphilis, whether or not it is specific for the disease depends in my opinion, simply on the question whether or not the spirochetes are accessible to the drug. Of course if some few or remote are buried deeply in the tissue away from the direct influence of the circulation they will survive, reproduce, and the patient will relapse.

It appears from the latest literature on this subject that the profession had decided that the intravenous method is the most practical and decidedly the best means of administering the drug.

While the intra-muscular injections of the alkaline solution seems to give the best results, but owing to its many dangers it has practically fallen into disuse. The method is very painful, pain usually lasting four or five days, also extensive necrosis, encystment of the drug, which defeats the very object of the treatment.

INDICATIONS.

Salvarsan is indicated in all stages of syphilis, with few exceptions, which will be mentioned under the head of contra-indications. I noticed in reading an article in the last issue of the *Journal of the A. M. A.*, from the

pen of Dr. Henry J. Nichols, Capt. Medical Corps of the U. S. Army, cites two cases of syphilis cured by one injection, or dose, of the drug, but he explained the cases as follows: one was an extra genital chancre of the lip with beginning eruption. This case was of two months duration, no previous treatment. Wasserman reaction positive before administering treatment. The same reaction showed negative for twelve months after the first and only dose of the drug. This only indicates the importance of an early diagnosis, and an early and vigorous treatment of syphilis during the primary and secondary stages.

It is too early to make positive statements in regard to the number of treatments necessary to cure a case of syphilis. The whole history of the practical use of salvarsan covers less than two years, the first year being spent practically in experimenting with the remedy, hence a cure, or how often the drug should be administered would be conjecture, and therefore we will have to depend upon the Wasserman reaction in this matter, but the opinion of men of experience on this subject, claim it best to use repeated doses, for instance, give two intravenous injections one week apart, with repetition of treatment after one month, but all cases should be carefully observed, and a Wasserman reaction made every 30 or 60 days, and only in this way will we ever be able to arrive at any definite conclusions as to whether or not we effected a cure.

The cure of syphilis with salvarsan, is a condition in which the drug comes in contact with the invading organism, and is supposed to kill the spirochetes or the spirillum of syphilis *en masse*, therefore we have a reaction from a large number of dead spirochetes liberated in the system, producing endotoxins, which are toxic, that produce symptoms as follows: headache, temperature, and nausea, vomiting and sometimes diarrhoea, which last as a rule from 6 to 10 hours, which passes off and patient is allowed to resume his duties after twenty-four hours unless reaction persists.

In regard to the preparation of the patients for administration of the remedy, it is best to have them remain in bed in the morning without breakfast, give salvarsan about 8 a. m., and have nurse to chart patient's temperature every hour. This should be done in every case as it is a therapeutic test of the efficiency of the drug.

CONTRA-INDICATIONS.

The contra-indications of its use are many and before administering it, the patient should be put through a very rigid examination to ascertain if any pathological condition exists, which would make its use hazardous;

don't use salvarsan in organic lesions of the heart, advanced cases of tabes dorsalis, and general paresis, syphilis of the nervous system, especially of the vital centers, grave kidney lesions, cachectic and debilitated persons, unless due to syphilis, and then in very small and ascending doses, aneurysm, optic neuritis, gastric ulcer, arteriosclerosis and other conditions where increased blood pressure may be dangerous.

With my very limited experience with this new drug I have never seen any bad effects, in fact my experience has been very gratifying along these lines, lesions disappearing in four to five days and patient gaining in weight and strength, and they all insist that they are well or cured as they term it, and when I mention the second, third or fourth dose, they begin to think I am trying to fleece them.

A word in regard to the history of Dr. Ehrlich's discovery of this remedy is like that of tuberculosis, diphtheria and many others. The disease was robbed of its mysteries after the germ was discovered that produced it. In 1903 Dr. Metchnikoff transmitted the disease to apes, which then started the movement that gave it its proper place among the infectious diseases, and threw it open to work along modern lines, which led Dr. Ehrlich to believe that a serum could be worked out that would conquer this menace to humanity. So in 1910 he made known his findings, and therefore salvarsan or "606" as commonly termed, was placed among syphilographers over the country who experimented with the above mentioned drug until to-day it fills the most important place in the treatment of syphilis.

In closing I want to say that salvarsan should be given in every case of primary and secondary syphilis. If it only renders the patient a safe member of society for a few months, therefore preventing the spread of this great enemy of humanity, we could class it as one of the greatest boons that was ever discovered along the lines of medical research.

Negative Results from Roentgenotherapy in Nephritis.—Galausino exposed a number of rabbits and guinea-pigs to the action of the Roentgen rays, striving to detect a curative action on experimental nephritis, but without any apparent result. He was never able to detect a difference between the behavior and findings in the kidneys exposed and in those of the control animals. Similar negative findings were obtained also in six clinical cases of chronic parenchymatous nephritis and one of transient mixed nephritis.

CARE OF PREMATURE CHILDREN.*

By W. Z. JACKSON, Arlington.

My purpose in writing a paper on this subject is not to tell you something new, but to arouse our interest in the care of premature children. I shall speak of the care and home treatment of them from the sixth to the seventh month.

At the Sloane Maternity Hospital, there were 85 cases treated as infants at term, and of these, 4 died, a mortality of 4.4 per cent. 145 were placed in cotton; of these, 12 died, a mortality of 8 per cent.

The appearance of a child from 24 to 28 weeks; subcutaneous fat begin to appear in the region of the neck, shoulders, and breast; the nails are represented only by firm folds of integument; the skin is very red, having the appearance of a mucous membrane. Children born during this period are able to cry softly.

From the 28th to the 32nd week the pupillary membrane disappears, the intense red color fades out, the subcutaneous fat becomes diffused over the body and the nails are developed as far as the finger tips. Children born during this period are viable.

There are three main principles in the treatment of premature children. First, the temperature immediately surrounding the child should be adapted to its requirements; second, its nutrition should be maintained by proper feeding; and third, the handling of or any other disturbance should be reduced to the minimum.

The temperature of the lying-in room should be carefully regulated and the child should be handled with the greatest care from the moment of birth. The rule that the cord should not be ligated until it has ceased pulsating, is here of special importance; meanwhile the child should be wrapped in something soft and warm.

Premature children should not be bathed but may be cleansed with soft cloths and warm sweet oil, as becomes necessary. The action of the skin may be improved by anointing the body every two or three days with sweet oil. Their clothing should be a napkin and a soft flannel shirt and they should be placed comfortably in bed.

Owing to their weakened condition and the sudden withdrawal of the constant nutrition they receive in utero, these children usually live from two to six hours only, unless they are given some nourishment and at this juncture our work and energy in home treatment is required.

As I stated in the beginning, these babies

*Read before the Carlisle County Medical Society.

cry very softly. If they do not receive nourishment from one to two hours after birth, their cry becomes a whine and gradually grows weaker until about the sixth hour, when life ebbs out.

I have been able to save three of these babies and know of no better way to give you the treatment and management of them than to report a case that I have just had.

On the 23rd of last June, I was called to see a lady whom I was expecting to wait on in September. I found her well advanced in labor and in about two hours she gave birth to two girl babies, weighing four pounds each. The last one was breech birth. The parents were very anxious to rear them as they wanted twins and were ready and willing to do all that could be done for them.

We dressed them in their napkins and soft flannel shirts; placed them in the bed, using hot-water bottles as artificial heat; put a thermometer between them and kept the temperature from 90 to 95. Their soft cry went gradually to a whine. I instructed the nurse to give them nourishment with a medicine dropper, which was done at once. Their whine ceased and they went to sleep. They were given nourishment four times during the night with the medicine dropper and this was continued in the same manner every two hours for the first three days and nights.

On the fourth day, we began to use a teaspoon and gave from two to three teaspoonfuls of Eagle Brand Malted Milk, 16 to 1, every two hours for two weeks—day and night. During the next two weeks we gave them five and six teaspoonfuls every two hours and when four weeks old put them on bottle nourishment every two hours 14 to 1. As they grew older, we made the nourishment a little stronger and fed them at longer intervals.

We anointed them every morning with sweet oil; but the most interesting part was the range of their temperature. It ran from 99 to 100 and occasionally 101.

When they were seven days old, one of them was considerably jaundiced. It was sick for several days, but with a little treatment it soon recovered. Afterwards, it had several attacks of gastroenteritis; and it was seized with a severe attack of this distress during the last days of August; its temperature went normal for the first time, sometimes below and remained that way until September the 5th, when it died.

The one that is living was three months and fifteen days old before its temperature went normal.

As I stated, at birth they weighed four pounds each. In ten days they had gone to three pounds each; but when one month old they weighed 4 and 4 1-2 pounds each and at

the end of the second month they weighed 5 1-2 and 6 1-2 pounds respectively. The weight of the one that died was 7 1-2 pounds, when it was taken sick. The other weighed 6 1-2 pounds when it was three months old and at the present time it weighs 12 pounds and seems to be well and hearty.

Another peculiar feature was that during the warmest weather, when we would take the hot-water bottles out of their bed they would grow cold all over. So, we had to be very careful as to the temperature in which we kept them. It required the closest attention day and night to save their lives.

I hope that my few remarks will stimulate the members of our society to give more attention to these little premature children and not to think because they are premature that it is useless to try to save them.

We never know what a life holds,

To save a life is great gain,

To save a life is our aim.

THE PRESENT STATUS OF CANCER OF THE UTERUS.*

By C. N. COWDEN, Nashville, Tennessee.

The problem of cancer is one of the most important before the medical or surgical world to-day. It is certainly on the increase, not only as a disease of modern life, but from other subtle and mysterious causes that, so far, modern science has failed to explain.

It is almost the only disease that is steadily and rapidly increasing among the civilized races of the world. Cancer at its present rate of increase will soon be more numerous and fatal than tuberculosis. With the aid of the International Congresses, medical associations, the press at large, health boards, woman's clubs and education of the public in general, we have finally begun to decrease the mortality from tuberculosis. One of the partial triumphs of the twentieth century. And yet none of these great influences for stamping out or limiting the spread of this disease has been placed on foot to bring before the laity or the greater part of the profession the known and accepted facts in regard to cancer and its cure. If we could get the laity to recognize the fact that one woman in eight and one man in 18 beyond 35 years of age, die

*Read before the Logan, Warren and Simpson County Medical Societies.

of cancer, they would at once become interested.

It has been shown by painstaking statistics compiled by Meek, that cancer of the uterus forms more than one-third the number of primary cancers. According to Kelley, out of 11,000 cases, reporting in fifteen years at Johns Hopkins for gynecological treatment, 412 were for cancer of the uterus. Crile estimates that we have more than 80,000 cases in the United States to-day, or practically one per cent. of our population at the present. This means of course, cancer of all organs of the body, but as stated above, cancer of the uterus easily leads the list in frequency.

It is certainly a very timely and interesting problem that confronts us to-day, and the question is, What have we done and what can we do to prevent its mortality, that in untreated cases is, practically, one hundred per cent?

Of course we ultimately hope to find the cause of the disease and so attack it at its source, and to this end thousands of dollars are being expended in careful and painstaking investigation, employing some of the keenest minds in our profession in research and experimentation. But so far, we have to say in all candor that the results from a practical standpoint have been universally disappointing.

At the present time it seems that the cause of this dread malady is as far from solution as it was years ago. But many of as seemingly impossible things have been done in the past, and many of our investigators believe that the solution of cancer is to be worked out at a very early date.

At the Southern Surgical and Gynecological Association that met in our city a short time ago, in the symposium on cancer by four different men of international reputation, four distinct views were advocated as to its etiology. One the microbe, one the traumatic, another heredity, and the other advocated the old Conheim theory, to which we must apply to all their theories the Scotch verdict "guilty, but not proven."

The most enthusiastic and prominent medical man would be disbarred from the profession and tabooed by his confreres, should he claim a single cure. Serum therapy and immunizing vaccines that have wrought miracles in combatting many diseases, have been of no help at all in the treatment of this disease. The X-ray and radium that at first promised so much, are now regarded by those who are competent to give an opinion as of being only in the experimental stage and of little or no value at the present time, except perhaps in the most superficial cases of skin cancer. To-day the surgeon only is dealing with it in some of its different stages.

Another embarrassing phase of the question is—we are sometimes asked as to the heredity of the disease. For instance, a mother comes to us suffering with cancer and asks if her daughter is likely to have it. Again, the daughter whose mother has died of cancer wants to know if she could have inherited it from her mother. Both practical questions. Parke sums up the answers as follows, "Perhaps there is some danger. But simply because of its liability of a transmission of a predisposition. It is not possible to inherit disease which was not present when the individual was born." But it is a well-known fact that different members of the same family develop the disease. We just had a fatal case of carcinoma pylorus, making the fourth in one family. The mother, sister and two brothers, all dying beyond sixty-five. That it is inoculable is denied by none, and many of us have seen it develop in the line of an exploratory incision or follow the tract of an exploring needle. That it is contagious seems probable when numbers of cases have been traced to certain houses, occurring so regularly among the occupants thereof, as to designate them "cancer houses."

The scope of my paper, however, is not to deal with the etiology of the disease so much as it is to deal with the practical side of it, and see if we can't formulate some plan or attitude in regard to the matter that will in some way lessen the mortality of this, most dreaded of all diseases that human flesh is heir to. And in order that we may the better and the earlier take up the discussion of the subject, I lay down a proposition that every case of primary cancer is a local disease, that there is, or was, a time in all malignant neoplasms when it was a harmless growth, and could be, or could have been removed, or cured. Again I think I am justified in saying that no well balanced open mind doubts for a moment that the only cure for cancer at our command to-day lies in its total destruction or extirpation by surgical means. And it is of the utmost importance that every member of our profession should know just what surgery has accomplished and what can be expected of it in curing this disease.

Let me for a moment call your attention to some of the most common forms of cancer. See what percentage of cures surgery gives, and endeavor to learn from them how the percentage of cures can be increased.

We cure cancer of the lip in practically ninety per cent of the cases. Why? Simply because we see it in its incipency in many cases, in fact, in the so-called pre-cancerous stage. Under these conditions the surgeon is practically triumphant in nearly every case. In the Johns Hopkins Clinic, 47 per cent. of all cases of breast cancer with the radical op-

eration have remained well for the three years' limit. In another group of cases that were not advanced far enough in which a diagnosis was only made by a microscopical section at time of operation, 96 per cent of cures were given against 100 per cent mortality if left alone.

We are again told by our pathologists that cancer of the uterus does not differ in its biology from cancer of the visible surfaces of the body, and could it be seen in the same stage, it would be just as amenable to surgical cure. But surgery can do no more. It has reached the limit, for certain it is that nothing more radical can be conceived than the procedure of Clark, Sampson and Wertheim, who have perfected this modern technique of major surgery.

If better results are to be obtained than we are getting to-day, success must rely on some other outside aid. And this aid is surgery, plus, *always plus*, an early diagnosis; and as the surgery pertaining to this condition is perfected, the diagnosis of cancer of the uterus involves more responsibility than any other phase connected with the subject. Every mistaken diagnosis, yes, even a delayed diagnosis, costs a human life, because the cancer in the mean time becomes inoperable.

Taking the statistics of Johns Hopkins again, they report that of the cases presenting themselves to the Clinic for treatment, 70 per cent of them have reached such an advanced stage of development that no operation save a palliative curriement could be considered, and in more than sixty per cent of these cases the history elicited by the patient, that it had existed for a period of six months or more, should have sent the patient to the doctor for consultation and advice. Hence, in order to lower our present mortality, our hope lies not entirely in the general practitioner who practically sees all of these cases first, but we must start a campaign of education among the women of our clientele, and there can be no doubt that the most important agent in the instruction of the public is the general practitioner.

We are agitating the question of tuberculosis in all of its phases before the public to-day, educating them and results are prompt and encouraging. Why not go before our womens' clubs with knowledge upon this subject, that thousands will, if they are not now, become interested in. If it does not touch them individually, it will enter their circle and claim as a victim some kindred or friend.

Almost all women, especially all married women, have a more or less intimate acquaintance with some physician with whom they can converse at one time or another on the subject of their own health or that of their relatives or friends, and in whose opinion

they place great confidence. If they have not, they should have, for anything else is false modesty and prudish. If every physician would take advantage of the opportunities offered him by such confidential relations with his patient, to point out to her the significance of a slight hemorrhage, or any change in the character of her menstrual discharge, or pelvic pain occurring about the time of the menopause, he would accomplish more toward diminishing the mortality of cancer than can be done by any other means at our command at present.

Freedom from pain leads many patients into a sense of security. The laity should be taught that cancer is a painless disease, pain comes late due to some complication. The danger lies in the fact that these insidious symptoms occur about the "change of life," and these women and not a few doctors, have had inculcated in their minds the idea that at this special time all sorts of irregularities occur and are of no significance or importance. The woman herself may be impressed with her condition, and consult one of her elder friends who assures her that it is only "change of life." She in many cases later consults her doctor, who reassures her that such changes mean nothing, and in a short time all will be well with her. In many this will be true, but in the meantime those cases in which the symptoms are due to incipient, malignant disease will have passed into the inoperable stage, and the only hope of relief will have been lost.

We should teach our patients that the menopause is a physiological process, not attended with any symptoms unless attended by some pathological complication of the generative tract. All women who have borne children, approaching the cancer age, should be impressed with the fact that upon the appearance of any of these slight changes, she should come for a thorough examination by her doctor, not once, but again and again, and this would at once result in the discovery of a great many of these incipient cases that could unquestionably be relieved by the surgeon's knife.

Hence, to make the attack upon cancer effectual, it must be done in an early diagnosis. And what have we to say about the early diagnosis of cancer? It is most difficult indeed, and in some cases impossible. Why is this? Is it the fault of the doctor, due to his lack of skill and experience? Why is it, and we are sometimes asked this by the laity, we are unable to recognize this disease? Russell Parke gives the answer, namely "cancer as such, has no distinct symptomatology."

The signs and symptoms that we see in our cases and read in our textbooks, are not those of the disorder itself, but of some of its de-

generative consequences. The inaugural signs and symptoms are wanting and hence the diagnosis is made perhaps after a long latent period. The symptomatology of cancer will have to go through the changes as did those of appendicitis, in which for a long time the symptoms attributed to this condition were not those of appendicitis at all, but those of a perforative peritonitis. The same has been the history of gastric and duodenal ulcer. They were not recognized as such until secondary complications had arisen, such as hemorrhage, stenosis or perforation. The same evolution has been passed through in gall-bladder pathology and an advanced step like the above is sadly needed in regard to cancer of the uterus, that we may be enabled to take advantage of the precious element, time, wherein lies the patient's only hope of escape by an early operation.

True it is then, that an early diagnosis is the most important phase of the cancer problem to-day. How to make the early diagnosis is the question. An enormous amount of research and investigation is being carried on to-day throughout the medical world to discover the precancerous pathognomonic symptom or group of symptoms that would lead us aught. In attempting to discover some distinctive indicator of early malignancy, the secretions and excretions have been diligently searched, but anything distinctly characteristic of urine, feces, gastric contents, etc., have been sadly wanting.

A comprehensive study of blood findings in many hundreds of cases of early or advanced cancer, forces one and all to the conclusion that diagnostic significance could not be placed upon the variations of the different constituents of the blood. The serum tests and those similar to Widal and Wasserman and others, have only given unsatisfactory results, and if they did, they are perhaps more difficult to make than a microscopic test that is usually made after all other symptoms are positive. These tests are all special and are required to be made by an expert pathologist. So by the time the patient is subjected to any of these technical tests, it is too late for surgical intervention.

It is our misfortune that it does not have a distinct symptomatology of its own. When you can feel it you may recognize it. But what is going to bring the patient to you for this digital examination? She must have some excuse that will cause her to seek advice, and after she comes, there is not one symptom produced by cancer, either early or late, which may not be produced by some other disease of the parts.

"Therein," says Parko, "we find our excuse for failure to recognize it early, and therein we find our difficulty of coping with

it." Right here, Tausig of St. Louis, in a recent article gives us some data after reviewing 41 consecutive cases, that will be of help to us.

In taking the history of the cases he gave special attention to the following points. First of all: "How long an interval elapsed between the onset of the first noticeable symptom and the date of the first consultation? Second: How many doctors failed to make a thorough examination at this first consultation? Third: How many have failed to recommend an immediate radical operation?"

He found that ten out of thirty-two women concerning whom accurate data was obtained, could safely attribute their death to the neglect or ignorance of the attending physician, and reports by contrast several of the cases in the series, where an early and thorough examination had been secured, an examination made, the radical operation advised and accepted, followed by a cure.

He sums up the article as follows: "The blame for the late recognition of uterine cancer rests mostly on the woman herself. In about 90 per cent. of the cases the carelessness or ignorance of the physician was entirely or wholly to blame. Only 20 per cent. of the cases presenting were operable with any hope of recovery."

Hence, under all circumstances the physician should insist on making an internal examination at once, if there is the slightest suspicion of cancer. Nothing should deter him, neither lack of time, his own convenience, nor lack of confidence in his technique or ability to make a correct diagnosis. Not even the fact that the patient is flowing at the time.

All this delays a diagnosis, and then the patient herself makes enough objections. Some women are ashamed, others afraid of pain. Others dread a serious diagnosis or the physician's counsel to undergo an operation. Others resort to any excuse that occurs to them, in order to escape the hated examination. We must be anxious to make a thorough examination and overcome every excuse or objection of the patient, and especially must this be the case where there is a suspicion that a given case might possibly be a cancer.

An ironclad rule should be made to insist upon not only a digital examination but on a visual inspection of the uterine cervix, and if any faint suspicion is apparent a resort to the means of a positive diagnosis should be demanded and a candid frank statement made to the patient. She is anxious and willing to accept anything for relief. Less than this is gross negligence on our part as physicians, and in the majority of cases we will be able to recognize the cancer correctly at the first ex-

amination, under almost all circumstances.

The practice of some doctors keeping under observation a patient presenting suspicious symptoms of cancer in the hope that the destructive tendency of the growth may show itself, is a gross error upon the part of the practitioner, and deserves to be censured more than the one who gets a poor result from reducing a fracture, for in the latter case it means only a useless member while in the former it means death in at least 80 to 85 per cent.

I have had occasion to observe that among experienced physicians two factors play an unjustifiably important role in the diagnosis of cancer. The cancerous cachexia, and the well known "forty years." Gentlemen, after the cachexia appears your patient is doomed beyond any hope, and as to age, it may occur at any period of a woman's life, from 25 on to extreme old age. But it is a fact that it does not occur more often about the climacteric period. Hence age must deserve some consideration in the possibility of cancer.

Another thing having some weight is the number of pregnancies, all agreeing that the disease is rare in the multipara. In fifty cases reported by Cullen, all had borne children but one, and she had a mechanical dilatation.

After consideration of these two factors, we come next to the consideration of the more significant signs of disease, and usually they are so insidious that by the time symptoms manifest themselves, the patient is on the borderland of inoperable cancer.

What we wish to do is to adopt some practical mode of procedure that will enable us to determine with some degree of certainty in patients with uterine diseases, whether or not malignant infiltration is present. Malignancy is always a chronic condition and there is always present infiltration or ulceration. In the cervix if there is induration, it can be felt. If there is ulceration or erosion, it can be seen. If this ulceration or erosion is within the cervical canal or fundus of the uterus, it will cause a troublesome discharge.

Called to see a patient with pelvic disease, if we find no infiltration of the cervix or fundus, no ulceration or erosion of the cervix, and no troublesome pathological discharge, we are safe in concluding that the uterus is free from any malignant trouble. When any of these signs are present, we must make a differential diagnosis.

To aid us, we make three classifications of symptoms: the early symptoms, the late symptoms, and positive symptoms. Among the earliest symptoms noticed by the patient, the one that brings her for consultation and advice is usually a bloody stain now and then between the menstrual periods. It is especially noticeable after sexual intercourse or any

undue effort or exertion. The patient when her attention is called to it, may remember her periods are a little more profuse than usual, and that she is flowing a day or two more. And to this is added, a slight increase in her leucorrhea if she has had one, or if not, a thin watery secretion makes its appearance, that is sometimes tinged with blood.

This discharge is very characteristic. It is due to over-stimulation of the muciparous glands in the neighborhood of the growth, non-irritating and without odor. Under a vaginal examination in this stage, the cervix is slightly enlarged, very firm, and sometimes glazed in appearance, with seeming increase in vascular supply, especially in the prominence and size of some of the blood vessels. The examining finger is usually covered with blood, and even brushing the surface with cotton will usually be sufficient to produce a slight stain.

Heitzman has given us at this stage a very simple and practical test with the copper sulphate solution. Soak a pledget of cotton in a ten per cent copper sulphate solution and apply it for a minute or two to the suspicious surface. If the lesion is a simple erosion, a bluish white coat will form without hemorrhage. By repeating the applications at intervals of a few days, the lesion will be healed. If the lesion is cancerous ulceration, the application will cause bleeding. A few days later another application is made, and the bleeding is more profuse, a diagnosis of incipient cancer is almost certainly correct, and will rarely fail to be confirmed by the microscope.

At this early stage there is a tendency to friability of the tissues. Your tenaculum hooked in the cervix tears out easily in contradistinction to a toughened condition found in almost all inflammatory processes and conditions except recent subinvolution.

You do not have pain, any great amount of hemorrhage, stinking, irritating, discharge, anaemia or cachexia in this stage. But in the late or second stage we have them all. The patient begins to have pains in the pelvis. The periods become so profuse as to amount to a hemorrhage each month, and often we have hemorrhages taking place between the periods. If the woman has passed the menopause and has a return of the periods as she terms it, it is almost pathognomonic of malignancy. The leucorrhoeal discharge becomes very much increased, develops a clinging, penetrating, stinking odor, and often becomes very irritating. The patient begins to show signs of ill health, grows anaemic from loss of blood, and then the telltale cachexia makes its appearance. The cervix is now hard and often nodular, with ragged edge, foul covered ulcers showing on the cervix, or the friable,

vegetating cauliflower growth begins to send out finger-like processes on the surface of the cervix and to fill the vagina that bleeds freely at the slightest touch.

A tenaculum hooked in the tissues, tears out easily, and signs of a breaking down of the tissues is very evident. But by this time, we have two cardinal, clinical features of cancer, namely, neoplasm and degeneration, and the diagnosis is easy. If one is absent, either the tumor or the ulcerative process, the diagnosis may be very difficult or clinically impossible.

Then comes the third and positive symptom, or rather reliable evidence, that which is educed by the microscope. Every cervix that is irregular, hard and nodular, should be regarded as suspicious, especially if it is eroded or ulcerated and bleeds easily. If this is found, a snipping should be taken for microscopical examination. This should be taken in the form of a wedge, including both the ulcer and some of the cervical tissue beneath. The cervix is practically devoid of sensation, and a specimen can be obtained with very little pain, or painless with a small amount of local anaesthesia, and for the future mental condition of your patient, it should be done without her knowledge. For almost invariably, if the patient is told we wish to remove a small portion of the uterus for examination, it will be declined.

The statistics of operation for cancer of the uterus offer many uncertainties. In some instances the surgeon has run very little risk. Selecting those cases in which an early diagnosis has been made, thereby they have been able to report a goodly percentage of recoveries. On the other hand, there are those who disregard statistics altogether, and operate where there is the slightest possibility of saving a patient. We are sometimes in error as to the stage of the disease, as in quite a number of cases in which the disease is apparently in a very early stage, upon examination, when the abdomen is opened, we find it impossible to remove all the cancerous tissue. And again, apparently widely disseminated areas are found to exist which when opened up are entirely confined to the limits of the organ.

The question might well be asked, when is a case inoperable? In general terms it may be stated, when a cancer of the uterus can be diagnosed unhesitatingly as such, by the touch, sight or history, it has progressed already to the borderline between possibility and impossibility of a cure, and perhaps there are more chances against a cure than for one.

In all cases where it involves the anterior vaginal wall behind the bladder, or the posterior vaginal wall, spreading towards the rectum, or where the glands in the broad liga-

ment can be palpated, or the mobility of the uterus is even slightly interfered with from induration or infiltration, or in other words, where it can be demonstrated that the process has passed outside of the organ itself, the case is not one for the radical operation, and if done will only bring surgery into disrepute with no benefit to the patient. This is the class of patients reported by Baldy, with a return in ninety-six per cent of cases operated upon.

This high mortality rate was not due to his technical ability, but to the time or stage when he saw the case. A considerable step will have been taken towards the desired eradication from the public mind that cancer is an incurable disease, when operators can be restrained from undertaking those unwarranted procedures; for the last state of the woman is invariably worse than the first, and surgery bears the credit of the failure.

But what can be done for these cases? I am convinced by a very limited experience that the use of the cautery advocated by Byrne is the simplest and most effectual treatment that can be used. When large areas of ulceration are present, the curette may be used to advantage. Then, after protecting well the vaginal walls from contact with the cautery, the entire surface of the cancerous mass is burned away, care being taken not to penetrate the cavity or any of the hollow viscera. One advantage over the escharotics and pastes is, no one can foretell how deeply they will destroy, and the curette is often followed by rapid dissemination through the lymphatics. The actual cautery effectually closes the open mouths of the lymphatics, and so materially interferes with the nutrition of the cancer cells, producing a retrograde metamorphosis in them, destroying to a great extent their activity and growth. Cauterization should be repeated as often as necessary to limit the growth. Tampons of ichthyol and glycerine should be used, and bi-weekly application of iodine to the ulcer after the eschar sloughs away.

Gelhorn, of St. Louis, uses the curette and makes application to the cavity of acetone, reporting several very interesting cases of inoperable conditions that were very much benefited by its application.

After these palliative measures, no matter of what they consist if thoroughly done, they are usually followed by good results. The hemorrhage is controlled, the pain is very much lessened, and with these relieved, the comfort of the patient is very apparent and the nutrition of the body very much increased.

It is unfortunate that women with inoperable cancer should be undesirable patients at most hospitals, as much can be done to miti-

gate their suffering and prolong their lives. It is indeed pitiful to see just how little is done towards ministering to these, of all patients the most miserable, and how frequently every shadow of hope is taken from them by some unfeeling friend or perhaps the doctor, by not withholding the truth as to their true condition. They deserve a great deal from us as practitioners of the healing art.

To recapitulate: Cancer of the uterus is a curable disease when seen early, by an operation with practically very little danger. Complete extirpation of the uterus is the only method of cure at the present time, but the percentage of cures is far below what it might be made.

Our only means at present to lessen the mortality is by a campaign of education directed first to the general public by the family physician, that they may recognize the early signs of this disease, and not neglect to consult the family physician upon the occurrence of these symptoms about the menopause.

Second, The family physician must be made to realize that any disturbance about the menopause is very significant, and must be thoroughly investigated to ascertain the cause.

The knowledge regarding the possible serious significance of certain trivial symptoms does practically no good to any one as long as it is confined to the profession itself. It must be known by those in whom cancer is liable to occur.

Third. It is time for the profession to realize, that any disturbance about the menopause is very significant and cancer is to be suspected. In other words, the lesson to be driven home is that cancer is to be suspected in the great majority of chronic conditions, in which the exact nature is not definitely known, and must be followed by exclusion or demonstration of the disease.

Lastly, we want to emphasize the ease of obtaining a specimen from the cervix or by curetting the cavity, for a microscopical examination. If we ever do any more for cancer than at the present, it must be done by an earlier diagnosis.

Interpretation of Uterine Curettings.—In order to inaugurate a reform, Frank says, the clinician will have to insist, in the first place, that the pathologist, who, as a rule, takes but a perfunctory interest in uterine curettings (aside from the possibility of carcinoma, chorio-epithelioma or other tumors) take cognizance of our more recent knowledge; in the second place, he will be obliged to check in himself the pernicious and deep-rooted tendency to ascribe a great number of heterogeneous pelvic symptoms to inflammation of the endometrium.

"THE OLD TRANSYLVANIA UNIVERSITY OF OLD KENTUCKY."*

By JACOB GLAHN, Owensboro.

It is a dirty and ungrateful bird, that be fouls its own nest!

In begging the pardon of this learned body, physicians of Daviess county and Kentucky, for the introductory sentence of this article, I will try to justify its assertion in the procedure of this essay.

Are the institutions of learning of Kentucky, especially of Medicine, or have they ever been, behind the times?

"By their works you shall know them!"

All things equal, Kentucky is, and always has been, averse to cant, false pretenses and learned assumption.

The pioneers of Kentucky, mostly Virginians, for Kentucky sprang from Virginia, and men from other Southern states, honest, fearless, many well educated, all very close observers of nature and men.

Men and women of this type are not slugs, as history proves, they performed almost miracles of endurance and hardships for the sake of home, civilization and culture, and Kentucky, *non plus ultra*, without an equal, and *nec pluribus impar*, a match for all, is the living example of perfection of any State in these great United States, all accomplished in less than one hundred and fifty years.

As beauty is a relative term and has to be studied individually, so even the development of States should be observed by the many on the ground and at a distance, so as to be careful not to slander our neighbors and friends. Study the history of the world and the development of the human race and see how slow the evolution of civilization progressed. Remember the thousands of years of groping in utter darkness! In fact there was no culture to speak of, only if there would have been any real culture, Greece and Rome would not have destroyed each other; so it was only a sporadic awakening of culture, in Greece and Rome amongst the millions of barbaric tribes of the world.

True culture and civilization does not destroy, but builds up.

After the immigrants crossed the eastern mountain ranges and the great forests and in quick order established homes, hamlets and cities, they, by the very nature of their blood and raising, saw the necessity of schools and universities. So the Old Transylvania University became a fact; I use the term in a large sense, as all institutions of learning to-day in Kentucky had their inspiration from "The Transylvania University."

*Read before the Daviess County Medical Society.

Transylvania as a word indicates its meaning: "Beyond, across the forests."

What a grand, deep, soulful meaning, a university, an institution of learning, forcing its way ahead of any other state or territory, across great mountain ranges and unknown forests, a university in the wilderness, "The old Heidelberg of America," for the education of the sons and daughters of the early settlers of Kentucky.

This shows Kentucky to be the actual vanguard of civilization and culture of any state west of the great mountain ranges of the east.

Kentucky was learned and great, when Pittsburg of to-day was yet Fort Douquesne; Cincinnati, less than a hamlet, Fort Washington, and Chicago a mere corral in a plain, Fort Dearborn; the rest of this country, as before indicated, was nowhere in comparison with Kentucky.

Clark, Shelby, Todd, Sevier, Boone, Daviess, Clay, Lincoln, Helm, Crittenden, Brackenridge, Flaget, Spalding, O'Hara, Harlan, Gross, McDowell, Cobb, Cook, Bell, Bodine, Palmer, Yandell, Holland, J. N. McCormack, Watterson and too many more illustrious names as to be named in this short address, are only a few chiefs who carried civilization, culture, science and literature, established Government in and influence far beyond the borders of Kentucky.

Is it possible, that one man alone, born and reared in Kentucky, who belongs, I am loath to state, to that keen-sighted, kindhearted, tenacious race without a country, cannot have a soulful understanding of that unselfish patriotism, which so many Kentuckians have proved, and stamps them as well as their descendants and their state with undying lustre and fame? Their descendants have upheld what their forebears began, look at our vast fields, our pretty villages, thriving cities and institutions of learning, of charity and sympathy; do they not speak for themselves in the highest terms of accomplished actions, attained in a comparatively short time with the mearest means at hand?

What state has produced greater soldiers, statesmen, teachers, jurists or physicians?

What state has produced greater philosophers than Kentucky? Whence did New York, Pennsylvania and other states of the East draw their leading professors and teachers from? You all know, then as now, from Kentucky!

Kentucky, the *sine qua non*, most brilliant and scintillating diamond in the galaxy of great states of this Union stands foremost in home life, culture, science and benevolent brotherhood; her children's hearts are leavened in sympathy of their fellowmen and neighbors, they are brought up in a high

sense of justice. The school teachers of the public as well as parochial schools are ladies and gentlemen in the highest sense of the word, mostly descendants of the before named pioneers. So the spirit of seventy-six is forever being propagated in our young, which bespeaks well for the future.

In Kentucky, thank God, commercialism has not overcome character as yet. We still ask of a stranger, who is he? not how much has he? A man is still a man in Kentucky. Freedom and emancipation of manhood is in the air in Kentucky. Look what sermons brooks, rivers, cliffs, woodlands, rocks, and dells preach!

Oh! physicians of Kentucky, are your hearts so callous as not to receive an inspiration, when you ride through the mountains, the rolling country, the sugar cane or hear the rustling of the ripening corn— or listen to the call of the whip-poor-will, or the cooing of the dove?

Gentlemen: This is a nation in the making, intrepid men and women from the whole civilized world have come here to establish a home; a home of freedom and peace, a home not tampered by petty jealousies and cowered by officials or uncongenial governmental paternalism.

All these people represent the best energies and thoughts of the countries they left behind. Many of them bring technical skill in many specialties and others well educated brains and brave hearts; a nation growing and building with such material is bound to become the headlight of the world, and older nations are setting up and beginning to take notice with astonishment and admiration.

We have to be doubly careful, as not to become overbearing in the eyes of the nations of the world, because such weakness belongs only to the shoddy rich and their servants, not to the real man.

The death rate of Kentucky as well as the calls for charity compare well with any of the older states, this proves that our physicians are not lacking in proficiency as compared with other states. Our laboratory equipment of our University has been unjustly criticised by one raised in Kentucky; because accused of being larking in a little glassware and such like utensils, just as well criticise women's fashions and clothes; they are good for show and a season, and especially who wears them. But after all, no laboratory alone ever made a good physician, a bedside practitioner, for it takes more than a little test-tube chemistry or microscope to make a man, an emancipated Doctor of Medicine.

Our highly salaried researchers in endowed institutions, were never physicians, bedside practitioners, they don't know anything about the symphony of the pulse of man in health

or disease, and since they do prate so much about the magnifying power of the microscope I often wonder and deplore, why not some one has discovered an instrument "a Nurenberger-Trichter" a mental microscope, that would instantly tell those wise investigators the relations to the natural law, of what they see under their focus on the slides, etc. Logic, the mental microscope, is hard to acquire, and takes years of hard work, observation and humble application, especially at the bedside.

No man, who has gathered these kernels of truth, cares for notoriety. The tendencies of serum therapy, as it is made notorious through endowment-institutions and serum-factories, is distinctly harmful to the science and art of medicine, especially so to the medical student and graduate in medicine of the new era, because science is ever evolving, therefore methods of treatment changing, and if this madness is persevered in, laboratories for the manufacture of serums, and endowment institutions will become the medical directors of men, and physicians, learned men are not needed any longer in the profession of medicine, a hypodermic syringe, a little package with instructions from serum factory to an excuse (save the mark) for a specialist, will constitute the eventual physician of the future.

If medical philosophy amounts to anything at all, in these modern times, it ought to mean this, that a weak solution of carbolic acid, fortified with a little chloride of lime and soda, as the momentary synthetic and fermentative disturbances may indicate, should replace all these very expensive products of the serum factories; for in its last analysis this is about all, antitoxins can contain and the actual benefit can only be derived from a few named chemicals; carbolic acid, water, lime and soda; but the last word along this line has not yet been uttered. But let us not be fearful or troubled for happily the American physician, and especially physicians of Kentucky are ever wide-awake to the truth and always on the alert as things turn up, they will not take everything as final or as absolute, what is handed down from New York, Chicago, or even from Europe.

Gentlemen of the Daviess County, Kentucky, Medical Society: Permit me, who knows you so well and who has lived among you and who worked with you in the same cause for so many years, to congratulate you, for the attainments you possess and high position you hold in the Kentucky State Medical Association.

NEWS ITEMS AND COMMENTS

ADAIR—Dr. S. J. Simmons, of Gradyville, is spending a few days in Louisville and Frankfort.

LEE—Dr. G. S. McDonald, of Beattyville, has moved to Estancia, New Mexico, where he will make his future home.

BELL—Dr. Mason Coombs, who has been taking a post-graduate course in New York, has returned to his home in Pineville and will open up an office there in a short while.

BOONE—Dr. Peddicord writes that there is one case of scarlet fever in Florence, Boone county, but that the household is under quarantine and they do not expect an epidemic.

BOONE—Dr. H. H. Hays, of Bullittsville, is in the Bethesda Hospital, Cincinnati, where he has recently undergone an operation for a diseased shoulder joint, caused by a dislocation received during the holidays.

BREATHITT—Dr. John Mason Kash, of Jackson, a highly respected physician of that place, died on January 30th, 1912, while on a visit to his daughter, Mrs. Floyd Days, at Winchester. His death was caused from paresis and acute nephritis. He was 74 years old.

CARLISLE—The many friends of Dr. John R. Owen, of Arlington, will regret to learn of his death, which occurred on March 8th. Dr. Owen was a member of the Carlisle County Medical Society and stood high in his profession. We extend our deepest sympathy to his bereaved ones.

FULTON—There is an epidemic of whooping cough at Hickman, many of the school children having it, and children in all the surrounding country around Hickman. In several instances the malady has been fatal. Many grown people are also suffering from whooping cough.

SIMPSON—Dr. M. M. Moss, who is the County Secretary of Simpson County, has gone to New York to take a post-graduate course in the Polytechnic Medical School and Hospital, after which he will attend the American Medical Association, at Atlantic City.

HART—Dr. J. H. Hester, of Munfordsville, the very efficient secretary of Hart county, has gone to Chicago to take special work in the Chicago Eye, Ear, Nose and Throat College and will probably be away six months or

more. Dr. J. J. Adams, of Munfordsville, will act as assistant secretary while he is away.

KENTON—At a meeting of the City Council of Covington, the ordinance creating the position of a bacteriologist in the Health Department was passed and the salary was fixed at \$800 a year. The ordinance reducing the salary of the Health Officer from \$1,800 to \$1,000 a year was also passed, and the two positions will now be filled at the same cost to the city that has formerly been paid to the Health Officer.

WARREN—Dr. W. L. Heizer, the Vital Statistician of the State Board of Health, gave an address at the Y. M. C. A., on March 9th, at 3 o'clock. Dr. Heizer has been a most acceptable speaker all through Kentucky and adjacent states, and it was a treat for the men of Bowling Green to hear his earnest presentation of facts coming straight from lessons of his own experience and discovery.

CLARK—Dr. R. W. Wood, who recently resigned the position of Assistant Superintendent of the Eastern Kentucky Insane Asylum, has located in Winchester. If there is anything in the old adage of "The more the merrier" Winchester should have a very jolly bunch of doctors, as there are twenty-eight engaged in practice at present.

BATH—Dr. N. T. Clark, of Olympia, is in the Good Samaritan Hospital at Lexington, suffering from appendicitis.

Dr. L. F. Robbins, of Salt Lick, is slowly convalescing after an all winter siege of a complication of diseases.

Dr. Dailey writes that they have had no epidemic of any kind this winter in his county.

DAVISS—Dr. W. E. Holmes took 3 1-2 oz. of carboic acid in his office at 7:30, March 4th; telephoned five blocks to his wife and told her goodbye, and was dead before any one got to him. He leaves a wife, one son, 22 years old, and a small daughter. They are well provided for financially. He was a graduate from the Jefferson Medical College in 1879; was a member in good standing of the Daviess County Medical Society.

WHITLEY—Dr. J. H. Barker, of Corbin, is spending a few weeks in New Orleans taking post-graduate work.

Dr. B. F. Tye has changed his location from Spruceburg, Whitley county, to Bush Creek, Knox county.

Dr. E. L. Harmon has moved from Jellico Creek to Spruceburg.

Dr. J. F. Bryant, Corbin, is at the bedside

of his uncle, who is very ill in Knoxville.

SCOTT—The Scott County Medical Society met on March 7th, at Georgetown. The chief topic was "Tuberculosis," to which the public had been invited. There was a good attendance of both doctors and laymen. Dr. Albert Frieburg, of Cincinnati, gave a very intellectual talk upon "Bone and Joint Tuberculosis." Dr. A. B. Coons, of Georgetown, read a paper on "Pulmonary Tuberculosis", and Dr. R. W. Porter, on "Incipient Tuberculosis".

FRANKLIN—Dr. Thomas Gardiner was on February 29, appointed by Governor McCreary a member of the Board of Control of the State asylums. The appointment of Dr. Gardiner is a good one, and he is intimately acquainted with this line of work. He served as superintendent of the insane asylum at Hopkinsville, under Gov. Bradley's administration, and was appointed a member of the board of control by Gov. Willson. His home is at Madisonville, Ky.

JEFFERSON—Dr. Ap Morgan Vance, one of Louisville's leading surgeons, who was seized with a hemorrhage of the nose on March 4th, is greatly improved, and it is expected that he will be able to leave the St. Joseph's Infirmary in a few days. For a time apprehension was felt, and a score of physicians were called into attendance.

Dr. Vance was at his home, 835 Fourth street, at the time he was seized with the attack. Efforts to stop the flow of blood were unsuccessful, and he was removed to the infirmary in order that he could receive prompt medical attention.

CASEY—News has been received by her relatives here of the death of Mrs. J. T. Wesley, which occurred at her home at Middleburg, Casey county. Mrs. Wesley was the widow of the late Dr. J. T. Wesley, who for forty years was one of the leading physicians of South-Central Kentucky, and who at the time of his death—some three years ago—was vice president of the Kentucky Medical Association. Mrs. Wesley's death was due to infirmities of old age. She was about seventy-three years of age. Three children, two sons and a daughter, survive. They are Dr. I. S. Wesley, of Liberty, and Mrs. Joe Williams, of Lincoln county. Taylor Wesley, of Highland Park, and Henderson Deabard, of 717 West Broadway, are nephews of Mrs. Wesley. The interment took place at Middleburg.

WHITLEY—The following program has been arranged for the next regular meeting of the Whitley County Medical Society, which will be held at Corbin, April 4th, at 11 a. m.:

Call to Order—President.....S. S. Brown
Address of Welcome...T. J. Ballard, Corbin
Response.....A. T. Slemmons, Jellicoe

SCIENTIFIC SESSION, 11:15 O'CLOCK.

Head Injuries...A. D. Willmoth, Louisville
Discussion....J. D. Adkins, Williamsburg
S. S. Brown, Mt. Ash,
J. F. Wilder, Wilton.

LUNCH 1 O'CLOCK.

SCIENTIFIC SESSION, Continued, 1:30 O'CLOCK

Pellagra.....S. B. Snyder, Jellicoe
Discussion.....L. O. Smith, Williamsburg
P. G. Petrey, Packard
J. S. Lock, Barbourville.

Public Lecture at Opera House, 7:30 P.
M., Subject, "The Problem of Living"

A. D. Willmoth

This program is so arranged on account of train service. We trust that all members and many others will attend this meeting and remain for the lecture.

M. W. STEELE, Secretary.

BOYD—At a meeting of the Boyd County Medical Society, February 20, 1912, the following resolutions were unanimously adopted:

Be it Resolved, That this society in recognition of the splendid service rendered the State of Kentucky by the State Board of Health, and by its able Secretary, Dr. J. N. McCormack, in the prevention of disease, the effective quarantine of infectious diseases, in the dissemination of information concerning public health and hygiene, and in the provision for the benefit of scientific laboratory work free of charge to the people of the State, does hereby unqualifiedly endorse the administration of the State Board of Health, and expresses entire confidence in the Board, both individually and collectively.

Be it further Resolved, That we protest against the enactment into law of House Bill No. 74, which proposes to change the method of selection of members of the State Board of Health. We consider that the present plan, whereby the appointments are made by the Governor from names recommended by the various medical organizations of the State, has resulted in the selection of the best available men, and any plan proposing a change cannot be productive of good. In support of this resolution we point to the enviable record of the Kentucky State Board of Health, and to its high standing and recognized merit both locally and nationally.

C. K. KERCHEVAL, Secretary.

HENDERSON—Governor McCreary will be asked to veto the bill recently passed by the

legislature taking out of the hands of the State Board of Health the power to examine cattle to determine whether they have tuberculosis. A joint meeting was held at the Y. M. C. A., of the county and city board of health, the county medical society and the anti-tuberculosis society to make a protest against the bill.

Strong resolutions setting forth the reasons why the bill should not become a law were adopted. It was decided to request Senator Starling Marshall and Representative Ben. E. Niles to use their influence to get the governor to veto the measure. Mr. Marshall was reached by telephone and agreed to telegraph to the governor and also gave his consent to have his name attached to a petition to be sent to the governor protesting against the bill.

Physicians in the city say that this is the most important question that has come before the anti-tuberculosis society since its organization. Mr. Niles could not be found and it is not known what position he will take. The resolution adopted is as follows:

Whereas, It is a well known fact that tuberculosis, or consumption, in cattle can be conveyed to man either by eating the meat or drinking milk from such cattle and that a large per cent of all cases of pulmonary tuberculosis in man derive their source of infection from the food eaten or the fluid drunk—and that the only way to discover tuberculosis in its early stages, in cattle is by what is known to science as the "Tuberculin Test", properly administered by a competent veterinary surgeon who has properly qualified himself to conduct such tests; and, that

Whereas, Very few counties in the state, except those containing cities of the first, second and third class, have veterinarians who are qualified to administer such tests, and if such tests are not properly made, they had best be not made at all; and,

Whereas, By the provisions of this bill no veterinary surgeon selected by the county authorities, can, or will be permitted to use the test for tuberculosis unless he discovers "physical evidences of tuberculosis in such cattle, in such county"—which is an absurdity upon the face of it for the reason that every properly qualified veterinarian knows that this is an impossibility except in the last stages of the disease. Many cattle which look fat and sleek, showing no physical evidence of disease, are at the same time infected with tuberculosis. In further view of the fact that a very large majority of the people of the state are beef and milk consumers they are by necessity exposed to the danger of acquiring this man-killing disease. Especially is this true of the helpless babies, whose principal and only food is dairy milk. Therefore,

in consideration of these and many other facts, which could be cited, be it

Resolved, By this joint meeting of the above association, that we deplore the passage of senate bill No. 56. Believing that said bill was passed under a misapprehension we vehemently protest against this bill becoming a law and earnestly entreat his excellency, Governor McCreary, to put his veto upon it. The commonwealth of Kentucky has a right, owes a duty and is under an obligation to demand that poisoned meat shall not be fed to defenseless men and women of the state and that her helpless babies be not compelled to drink milk containing the tubercle bacillus.

"Are not two sparrows sold for a farthing?" Fear not therefore; ye are of more value than many sparrows."

Is not the life of ONE CHILD of more value than many tuberculous cows?

W. L. THOMPSON, Mayor.

JAMES E. RANKIN, Chairman.

D. O. HANCOCK, Secretary.

MERCER—The following official statement was issued during the recent epidemic of Cerebro-Spinal Meningitis, in Mercer county, by the State and County authorities and local physicians.

"Cerebro-spinal meningitis or "spotted fever," like consumption, typhoid fever and many others, is a germ disease and therefore is impossible to contract unless the seed of the disease becomes planted in some manner in the individual. The disease is largely distributed by lodgement of these germs in the nose or throat. They may be inhaled with the air or they may be contained, as some claim, in the water.

"It is a disease of damp, cold weather and a "crowd disease." Rooms closed tightly and darkened as usually kept in winter, are excellent places for the diseased germ to breed, and it is found that the larger number of cases develop in such ill-kept, unventilated rooms, and most epidemics occur during the winter, late fall, and early spring months.

"Before the discovery of Flexner's Serum the disease claimed about 75 per cent. of the victims, and terminated speedily in death. Since the serum was discovered and promptly used, the death rate has fallen to about 25 per cent. The earlier the serum is used, the more chance the patient has to get well, and the shorter and milder the course of the disease. The disease is not highly infectious like measles, whooping cough and many other diseases. One or two may be the only ones of a large family to contract the disease.

"In the presence of an epidemic in any community the following directions are advised to be followed in consideration of the

patient, family and the community:

THE PATIENT

If possible, should be removed to an Emergency Hospital. If not, he should be kept in a well ventilated, sun-lit room, carefully guarded, by a trained nurse, from the rest of the household—no one being permitted to enter or leave the room except the physician and nurse who should use the same precautions to prevent the spread of the disease as they would for small-pox, diphtheria, scarlet fever, and other dangerous communicable diseases.

THE FAMILY

Should remain in the house and permit no one to enter or leave the place until declared safe by the Health Officer.

"Should sleep and live in well ventilated, well lighted rooms, blinds removed and ventilation being effected by raising or lowering the windows, care being taken to keep the room comfortable and warm.

"Disinfectant solution, approved by the Health Officer, should be sprinkled on the floors, and raising of dust avoided as much as possible.

"The throat should be frequently gargled with one part of Liq. Antiseptics, U. S. P. to four parts of water, two parts of Peroxide of Hydrogen. The nose should be sprayed with the same solution.

THE COMMUNITY

Should insist that thorough cleaning up of the town be done at once, a day to be set apart on which alleys should be cleaned up, back yards, cellars, privies, cleared of filth and rubbish and disinfected with freshly slacked lime. If the drinking water is not of known purity it should be boiled before use. Living rooms constantly well ventilated and sunned, as these two agents are very destructive to the germs.

"There have been altogether in the community only three cases, none of which lived in the town limits, and these are all cases of Cerebro-spinal Meningitis as has been proven by the report from the Laboratory of the State Board of Health. The family and houses are under strict quarantine. No new cases have developed and it is believed that there need be felt no anxiety that the disease will become scattered. In the meantime children should not be allowed to congregate until recommended by the Board of Health."

W. L. HEIZER,

State Registrar Vital Statistics.

J. TOM PRICE, Chairman.

W. H. WITHERSPOON,

C. B. VANARSDALL,

Board of Health.

J. B. ROBARDS,

W. D. POWELL,

T. O. MEREDITH,

C. P. PRICE.

WARREN—Dr. A. H. Abernathy, of McKenzie, Tennessee, has moved to Bowling Green and was unanimously elected a member of the Warren County Medical Society.

CHRISTIAN—Dr. W. M. Bassett, of Oklahoma, is now located at Pembroke. Dr. Bassett went to Oklahoma just after his graduation, in 1907. We welcome him back home.

Miss Mamie McGuire, the widely popular nurse, underwent a complicated operation for appendicitis in a Nashville infirmary. Last reports she was doing nicely.

WARREN—The Warren County Medical Society met in regular session in the council chamber of the City Hall March 13th, with Dr. T. O. Helm presiding.

Dr. W. S. Weaver made an interesting discussion on "Goitre," after which the question of a public abattoir was discussed.

A committee composed of Dr. F. D. Cartwright, chairman; Dr. F. D. Reardon and Dr. G. E. Huddle were appointed to go before the City Council and suggest the building of a public abattoir, which this committee will do at the regular meeting on Monday evening March 18th.

All the members of the State Board of Health with the exception of Dr. George Fuller, of Mayfield met in session at the State Board of Health's office on Normal Heights. The general routine business was transacted. Honorable Lawrence Fynn, Chairman of the State Railroad Commission is also here, and together with him, the members of the board visited the L. & N. station and made a thorough inspection of the grounds and building, but gave out nothing for publication.

Dr. J. N. McCormack was host to the board at a delightful luncheon served at the noon hour at his home, corner Twelfth and State streets.

THE FORUM

To the Editor:

I was very much interested in Dr. Ellis' article in the February issue of the JOURNAL. This is a subject in which I have been profoundly interested in and especially that part in which he refers to the sterilizing of the criminals and defectives, this is the key to the situation, and will do more to empty our asylums, penitentiaries, and other state institutions than everything else combined.

Except that part where he is in favor of requiring parties to have a certificate of sound bodies and mind before they can get license to get married, this I think is wrong for when you refuse license to marry you license licentiousness. I say let them marry so long as

they can make a living for themselves but don't let them raise a family. There should be no limit to the practice till every criminal and defective on the face of the earth is sterilized.

This put into general practice would revolutionize the world and would do more in one year toward checking degeneracy than all other means combined will do in ten. And the readiness by which people will co-operate is the main feature you will only have to lead them into the true light of the subject. I think Dr. Ellis is right when he says that it is the undesirable who raise the largest families those who are the least capable and able of raise and educate them, and it is not because they want them but to them there is no way out of it, and it will not take much to convince this class that it is not prudent for them to raise a family.

You convince by real example someone who has tried it who they have confidence in, that it does not deprive them of a single pleasure of married life, except the child, and you won't have any trouble in getting their cooperation.

I have been studying this question for fifteen years and have done some research work along this line, and have some living subjects and have had the pleasure of studying the subject down to the present. I will say that I am the first man in the world who advocated the sterilizing by dividing the vas deferens for the limitation of the reproduction of the defective and undesirable human beings.

This is the only way by which we can have absolute control of the reproduction of human beings, which we ought to have, and I think this would be without giving offense to the Creator.

This is a little operation which can be done in the office without any pain and without any danger and does not deprive any one of any pleasure which he would enjoy without it.

This should be speedily brought into practice, and we would soon see our asylums beginning to empty and our criminal courts would have less to do, and the various children's homes would not be so crowded. In fact I think it is the most important and rational subject that the world has discussed in the last several decades.

R. L. FORD.

Cesarean Section and Its Alternatives.—Peterson emphasizes the fact that abdominal Cesarean section is always exceedingly dangerous in the presence of sepsis; that at times it is absolutely unjustifiable, craniotomy on the living or dead child being the preferable procedure.

COUNTY SOCIETY REPORTS

Boyd—The Boyd County Medical Society held its annual business meeting December 11, 1911, and elected officers for 1912 as follows:

President, P. C. Layne; Vice President, W. O. Eaton; Secretary, C. K. Kercheval; Treasurer, H. S. Swope; Delegate, W. O. Eaton; Censor, J. D. Mutters.

Meeting will be held on the first and fourth Monday of each month in Lordier's Hall, Ashland.

C. K. KERCHEVAL, Secretary.

Mason—On February 26 a meeting to reorganize the Mason County Medical Society was held in the G. A. R. Hall at 2 p. m., at this meeting were present Doctors Harover, Brand, Samuels, Cooper, Taylor, Taulbee, Yagel, Quigley and Patton (colored).

The following officers were elected: Woodson H. Taulbee, President; Arvid O. Taylor, Vice President; A. R. Quigley, Secretary-Treasurer; Councilors, J. R. Cooper, W. S. Yagel and J. H. Samuels; Delegate, S. R. Harover; Alternate, Leslie Brand. The Maysville Academy of Medicine was also reorganized and will hold weekly meetings on Wednesdays at eight p. m., the regular County Society meets the first Monday in each month at two p. m.

A. R. QUIGLEY, Secretary.

Pendleton—The Pendleton County Medical Society met at the office of Dr. John E. Wilson in Butler, with the following members present: Drs. P. N. Blackerby, Caldwell, Clark, Hopkins, Kendall, Nichols, John E. Wilson, Woolery, W. H. Yelton, Geo. F. Henry. The meeting was called to order by President Blackerby, and after reading of the journal and roll call, we entered into business. After the usual reports of new and unfinished business we got down to a report of clinical cases, and we had some very good reports of interesting cases.

T. C. Nichols read a very good paper on "Rheumatic Fever," which was discussed by several members present.

H. C. Clark next read a paper on the subject of "Perineorrhaphy." This paper was also discussed by nearly every member in attendance.

This closed the reports of clinical cases and the reading of papers and the society then adjourned.

W. A. McKENNEY, Secretary.

Campbell-Kenton—The regular monthly meeting of the Campbell-Kenton County Medical Society was called to order on January 18, 1912, by R. Lee Bird, in the absence of the President, J. G. Furnish.

The minutes of the previous meeting were read and approved. The application of Dr. Nellie

Danks was received and referred to the Board of Censors.

The Chair appointed the following Committee: W. W. Anderson, R. M. Rankin and J. G. Furnish to draft resolutions of protest against the repeal of the Vital Statistics Law, the mode of appointing the State Board of Health and the Optometry Bill.

The paper of the evening: "Acute Otitis Media, Cause, Complications and Treatment," was read by Wm. J. Thomassen, and discussed by Drs. Bledsoe and Behrman.

Members present, twenty-five.

The society adjourned to meet February 16, 1912.

R. M. RANKIN, Secretary.

Tri-County Medical Society—(Logan-Simpson—Warren).

To be held in Bowling Green, Tuesday, April 9th, 1912.

PROGRAM.

The Necessity for an Exact Diagnosis in Cardiac Lesions Finis London, Woodburnville.

To open discussion, J. R. Crittenden, Gordonville. Important Etiologic Factors in Gastro-Intestinal Diseases of Children

C. L. Venable, Franklin.

To open discussion, F. E. McCann, Gold City. The Practical Clinical Aspects of Anaphylaxis

N. C. Witt, Franklin

To open discussion, F. D. Reardon, Bowling Green.

Dietetic Treatment of Typhoid Fever,.....

D. G. Simmons, Adairville

To open discussion, J. C. Douglas, Franklin.

Recent Advances in the Physiology of Digestion L. B. Wilkerson, Russellville.

To open discussion, L. H. South, Bowling Green.

The Diagnosis and Treatment of Placenta

Previa T. W. Stone, Bowling Green

To open discussion, J. K. W. Piper, Russellville.

Christian—The regular monthly meeting of Christian County Medical Society was held in the City Court room, Hopkinsville, Tuesday, January 16th. J. L. Barker in the chair, and the following members present: J. L. Barker, W. A. Lackey, Austin Bell, F. M. Stiles, G. W. Lovin, J. Paul Keith, S. H. Williams, L. A. Tate, F. M. Brown, H. W. Watts, J. H. Price, O. L. Barnes, and W. S. Sandbach.

The minutes of the last meeting were read and adopted.

F. H. Bassett's application was voted upon and unanimously received. J. L. Barker presented the application of W. H. Watts, which was referred to the Board of Censors till the next meeting.

The president called for report of cases: Drs. Lackey and Bell reported a case of iodine poison with recovery. Dr. Sandbach reported a case of typhoid complicated with abortion, now in the

sixth week. All the members present took part in the discussion.

L. A. Tate read a very interesting paper on "A General Practitioner's Laboratory." The essayist emphasized the importance of the laboratory, it being much easier to make a correct diagnosis. It was discussed by Drs. Keith, Bell and Stites. Motion was made and carried to send it to the JOURNAL for publication.

The Committee reported the annual program which was read by the Secretary, who will have it printed and placed on the desk of every physician in the county.

No further business the meeting was adjourned to meet the third Tuesday in February.

W. S. SANDBACH, Secretary.

Ohio—The Ohio County Medical Society met in the office of Dr. S. D. Taylor, Beaver Dam, Wednesday, March 6th, at 1:30 p. m. Members present: Drs. S. D. Taylor, J. N. Taylor, J. O. McKinney, E. W. Ford and Oscar Allen. Bad weather having prevented our meeting in December and January, the first thing in order was the election of officers for this year. The following were elected: J. N. Taylor, President; S. D. Taylor, Vice President; Oscar Allen, Secretary-Treasurer; E. W. Ford and J. O. McKinney, Censors for one and two years respectively. Applications for membership were read and referred to the board of censors from F. B. DeWitt, Rockport; E. B. Pendleton, Hartford, and Willard Lake, Simmons. Motion made and carried that we meet again at Beaver Dam, April 4th, 1912, at 1:30 p. m.

S. D. Taylor reported a case of "Atresia of Vagina," in which he recommended a complete hysterectomy. We hope to have a report from this case next meeting.

E. W. Ford read an excellent paper on "Treatment of Tuberculosis" which was discussed by Drs. J. O. McKinney, S. D. Taylor and F. B. DeWitt.

Papers for next meeting: "Early Diagnosis of Tuberculosis," J. O. McKinney, Taylor Mines. "Vaccine and Serum Therapy," S. D. Taylor, Beaver Dam.

Adjourned to meet April 3rd.

OSCAR ALLEN, Secretary.

Christian—The Christian County Medical Society has arranged the following program for the entire year:

January 16—W. A. Haynes, "Pneumonia;" L. A. Tate, "General Practitioner's Laboratory;" J. B. Jackson, (Quiz) "What is the best medical treatment for Tuberculosis?"

February 20—M. E. Croft, "La Grippe;" C. B. Woosley, "Prostatic Hypertrophy;" Austin Bell, (Quiz), "Pneumonia."

March 19—W. W. Durham, "Symptoms and Diagnosis of Diphtheria;" F. M. Brown, "Treatment of Diphtheria and its Complications;" J.

W. Harned, (Quiz), "Prostatic Hypertrophy."

April 16—E. L. Gates, "Scarlet Fever;" J. H. Rice, "Gonorrhea;" D. H. Erskelston, (Quiz), "Typhoid Fever."

May 21—G. W. Lacy, "Management of Normal Labor;" N. C. McGraw, "Management of the Complications of Labor;" J. E. Stone, (Quiz), "Obstetrics."

June 18—T. W. Perkins, "Surgery at the Home;" F. M. Stites, "Summer Diarrhoea and Infant Feeding;" B. A. Caudle, (Quiz), "Summer Diarrhoea and Infant Feeding."

July 16—G. W. Loran, "Appendicitis;" F. P. Thomas, "Cause and Treatment of Spasms in Children;" F. H. Bassett, (Quiz), "Gonorrhea in Male and Female."

August 20—J. E. Johnson, "Smallpox;" H. C. Beazley, "Tonsillotomy;" W. A. Lackey, (Quiz), "Syphilis."

September 17—J. F. Stone, "The Menopause;" J. Paul Keith, "Management of Valvular Heart Disease;" O. E. Wright, (Quiz) "Dysmenorrhea."

October 15—O. L. Barnes, "Acute Articular Rheumatism;" A. H. Edwards, "Superficial Diseases of the Eye;" J. R. Paine, (Quiz), *Materia Medica*."

November 19—R. F. McDaniel, "Otitis Media;" J. A. Southall, "Fractures;" S. H. Williams, (Quiz), "Business Side of the Practice of Medicine."

December 17—Election of Officers for 1913.

J. L. BARKER,
W. A. LACKEY,
W. S. SANDBACH,

Committee.

Fleming—The Fleming County Medical Society met in Flemingsburg, February 21, 1912, with C. W. Aitken, President, in the chair. Members present: Drs. Brice, Robertson, Garr, Vice, O'Bannon and Bailey, (colored). The minutes of the previous meeting were read and approved.

E. R. Bailey was made a member of our society.

E. T. Buntins' application for membership was read and referred to the Board of Censors.

It was moved and seconded that the vote to change the time of meeting from once a month to once in two months be postponed indefinitely. Carried.

T. B. Vice reported a case of an undeveloped enlargement of the metacarpophalangeal articulation of index finger.

C. R. Garr reported a case of "Adeno Fibroma of the Breast," patient a girl 15 years of age. In operating not a blood vessel had to be tied. The tumor weighed fifty pounds. She made an uneventful recovery. He also reported a case of fatty tumor, operation and recovery. The presentation of these cases brought forth an interesting discussion, all the members taking part, which made one another feel it was pleasant to be here.

It was suggested that the subjects to be discuss-

ed by the society he placed in the hands of the Secretary one week before the time for our next meeting, by so doing it will enable the secretary to notify all members that they may come prepared to bring out all the points bearing on the subjects.

J. B. O'BANNON, Secretary.

Franklin—The Franklin County Medical Society met in the office of Drs. Williams and Mastin, March 4, 1912. Present, President Mastin, Dawson, Garrett, Kellar, Heilman, Williams and Minnish.

Minutes of the previous meeting were read and approved.

Balloting on applications for membership of Drs. E. E. Ronle and A. Stewart, resulting in their election to membership.

H. S. Kellar reported a case of "Typhoid Pneumonia."

W. F. Minnish reported an interesting case of "Typhoid Fever."

W. B. Dawson reported a case of "Infantile Paralysis."

All were discussed exhaustively.

U. V. Williams then said he had heard of "Foetus in Utero," having been often shot with a curette, but of only one as having been shot in utero with a 44 calibre Colt revolver and called upon Dr. Heilman to verify case which occurred in his practice—who said four week ago an Italian woman in a Dago camp of workmen on construction work building a turnpike near Frankfort, who was at full term pregnancy, and was a medium sized woman with a very largely distended abdomen. He was called to attend a case of labor, when he arrived he found the woman in pain with hemorrhage but was evidently not in labor. None in the camp could speak English, not even United States, except a small lad twelve years old, who said she knocked the pistol off the table herself, not knowing she had been shot, but the boy said the "gun went off."

On examination the doctor found a wound of entrance of the ball immediately above the symphysis pubis and lodged beneath the skin at the ossiform cartilage. Patient was removed to hospital and eight hours afterwards a laparotomy was performed and a hysterectomy uterus and adnexa removed. The ball had passed entirely through the uterus and placenta in its longest diameter of the mesentery and wounding the bowel but not penetrating the intestine, passing in and through the right shoulder and through the elbow of the foetus and abdomen and breaking the left hip and pelvis bone. All efforts failed to resuscitate the child and the verdict was death by accidental gunshot wound.

The woman made a very happy and uneventful recovery and in four weeks was able to resume her duties as cook in a shanty of Dago workmen.

U. V. WILLIAMS, Secretary.

Campbell-Kenton—The monthly meeting of the Campbell-Kenton County Medical Society was called to order by the President, J. G. Furnish, on the evening of February 16, 1912.

The minutes of the previous meeting were read and approved.

R. M. Rankin reported a case of "Displaced Heart."

The Board of Censors reported favorably on the applications of Dr. Nellie Dunks and Dr. Spillman, and both were unanimously elected to membership.

The Committee on Legislation presented the following resolutions:

"Whereas, one of the most important duties of a State is the conservation of the health and vigor of its citizens, and

"Whereas, the efficiency of this service is endangered by certain proposed legislation now pending,

"Therefore, be it resolved; by the Campbell-Kenton County Medical Society, that we earnestly protest against the passage of the Optometry Bill as legalizing the practice of medicine by those not properly qualified, commercializing the care of the afflicted, and risking the vision of our people, in the hands of those, who have no means of knowing the far-reaching significance of many eye defects.

"That we likewise protest against the proposed repeal of the Vital Statistics Law as a backward step from the stand of enlightened advancement taken two years ago, and before the marked benefits of that advance have had full time to become manifest.

"That we also protest against the proposed change of methods of selecting members of the State Board of Health as subversive of public interest and tending to partisan political service, rather than efficiency for the public welfare; and hereby express our belief that the animus of this proposed change is personal and political, rather than for the good of the service.

"Therefore, be it resolved; that a copy of these resolutions be sent to each Senator and Representative of Campbell and Kenton Counties, requesting them to vote against said bills, and use their best efforts to defeat same."

W. W. ANDERSON,

R. M. RANKIN,

J. G. FURNISH,

Committee.

E. A. North read a paper on "Relation of Infant Feeding to the Future of the Race."

W. W. Anderson, J. A. Davis, Pythian, J. D. Davis, Struble, Fishback, Walters, Rankin, Wilson, Bauar, Caldwell, Furnish, Ryan and Stine, took part in the discussion.

Adjourned to meet March 21, 1912.

JAMES A. RYAN, Secretary.

Carlisle—The Carlisle County Medical Society met in regular session at Arlington on

March 5th, 1912, in Dr. Hoeker's office, President T. J. Marshall, presiding.

On account of bad roads and weather, the attendance was small.

Those present were, Drs. T. J. Marshall, G. W. Payne, W. L. Mosby, R. T. Hoeker, W. Z. Jackson and J. F. Dunn.

R. T. Hoeker lead in a short prayer, after which the minutes of the previous meeting were read and adopted.

The Committee on Arrangements reported and was discharged.

W. L. Mosby, Payne and Dunn were appointed to examine a patient of J. F. Dunn's.

The program of the day was next taken up.

W. L. Mosby read a paper on "Cerebro-Spinal Meningitis." He gave the etiology, symptomatology and pathology in a clear and distinct manner. He gave the statistics of 49 counties of Texas in which there were 550 cases with 210 deaths. He recommended opium and bromides for rest; hot baths with ice bag to head. Thinks serum best of all.

G. W. Payne opened the discussion. He said he believed the serum treatment ideal but not practical with the country doctors.

T. J. Marshall insists if the scourge reaches us, that we quarantine and use lumbar puncture.

J. F. Dunn uses opium persistently although authorities state that it is contraindicated.

W. Z. Jackson reported a bad case in a child in which he was giving 4 drops of tr. gelsemium and one teaspoonful of a bromide solution, and the nurse through a mistake gave a teaspoonful of the gelsemium and 4 drops of the bromide. He never noticed any untoward effect from the large dose but the child at once began to improve and made a complete recovery. The result was that Dr. Jackson immediately ordered an abundant supply of gelsemium.

R. T. Hoeker also took part in the discussion which was closed by the writer.

J. F. Dunn read a paper entitled "Iritis as Seen and Treated by the General Practitioner." Most all present took part in the discussion, which was closed by J. F. Dunn.

R. T. Hoeker, last but not least, read a paper on "How Do and How Should We Treat our Fellow Practitioners?" It was one of the most beautiful papers ever read before our society. If every one would follow his instructions all the malice, strife and hatred that today exists in the medical profession would be wiped from the face of the earth, and our profession would be a little heaven on earth, but, we of little faith are afraid this can never be.

By motion our meeting will be held quarterly as formerly.

Our society adjourned to meet again in June.

J. F. DUNN, Secretary.

Bell—The Bell County Medical Society met at Pineville, March 8th, at the office of Dr. Edward Wilson.

The following members were present: Drs. Brosheer, Foley, Coombs, Hopkins, Wilson, Gibson, Bingham, Morehead, Flannigan, Hason, Hendren, Schultz, and Nuckols. Dr. J. S. Locke, of Barbourville, was also present as a visiting member.

The minutes of the previous meeting were read and approved. The committee appointed on county and municipal practice, presented the following schedule of fees to regulate such work:

"In regular medical cases, where the physician is ordered by the proper authority to take charge of a case, his fee shall be at the rate of two (\$2.00) dollars per visit within the radius of one mile, and one (\$1.00) dollar for each additional mile.

"In epidemic diseases, such as smallpox, his fees shall be at the same rate, for a single patient, and one (\$1.00) dollar additional for each additional patient at the same house.

"After all contagious diseases, where fumigation is necessary, an additional charge of five (\$5.00) dollars shall be made for fumigating.

"All surgical work shall be charged for at the usual prices prevailing in the same locality, for the same class of work. Or better still by special agreement.

"In ordinary obstetric cases, where the physician is not detained longer than four hours, the charge shall be ten (\$10.00) dollars.

"In difficult and instrumental deliveries, or where the physician is detained longer than four hours, the charge shall be twenty (\$20.00) dollars."

A resolution was passed directing the secretary to write Congressman A. O. Stanley in regard to the Public Health Committee.

W. G. D. Flannigan presented an interesting clinical case.

Jacob Schultz read a very timely and interesting paper on the "Use of Salvarsan in the Treatment of Syphilis." His paper was discussed by several members of the society, and a closing by Dr. Schultz.

J. S. Locke was called on to give the progress of the "Hookwork" investigation and a committee was asked for to confer with the fiscal court in regard to giving some aid in defraying the expenses of treatment for the poor. Drs. Bingham, Foley and Wilson were appointed as the committee.

There being no further business before the meeting the society adjourned to meet at Midleboro in April.

O. P. NUCKOLS, Secretary.

ORIGINAL ARTICLES

SOME RECENT ADVANCES IN MEDICINE.

(AN ADDRESS.)

By J. B. MARVIN, Louisville.

Allow me, at the outset, to disarm criticism by stating that I do not intend to give you anything original, but to simply give you a few points, boiled down, in connection with recent advances that have interested me most as an internist.

PELLAGRA.

This is a disease that is increasing in different sections of the country and at a rate that demands serious consideration. It has been reported in more than thirty States; its area is extending, and it is a menace to a large number of people. There are at present more than 2500 cases of pellagra in the South alone. It is probably the most important public health problem of the present day, and calls for urgent and early solution. A report of every case should be required by law. It is now reportable in only four States and required by law in only one. No appreciable advance has been made in our knowledge of its etiology or prevention. The maize theory has been attracting less and less attention. Recently, some one—without justification, I think—has suggested cottonseed oil as a possible etiological factor. Sanborn's hypothesis, that it is due to the Buffalo gnat, or other species of fly, and Alessandrini's theory that it is water-borne, probably by the trematode

Filaria of sprue, etc., have not received confirmation.

However, we have learned a few facts about pellagra. In the United States it seems to be more a disease of the country than of the city, and appears to be confined to certain regions. It occurs more frequently in the female sex. All the cases that I have seen, outside of institutions, have been in women, and, furthermore, in women of the better class.

As in all diseases that have attracted widespread attention, we have perhaps, in many instances, erred in being too quick to make a diagnosis of pellagra, but I can now readily recognize a number of cases of this condition which I failed to diagnose at the time. The diagnosis in a well marked case is generally easy. Bear in mind, however, that the course of the disease is marked by periods of improvement followed by recurrences at certain seasons of the year. It is essentially chronic. I commend to you a simple rule of "three d's" (to which my personal experience has led me to add a fourth;) namely, digestive disturbance, dermatitis, delirium, and death.

Various forms of treatment have been suggested. Recently it has been claimed that salvarsan has a good effect. I have tried soamin and other arsenic preparations, urotropin and quinin. The dermatitis seems to be the most easily controlled feature of the disease.

• • • •

I pass over cereb-ro-spinal meningitis and anterior polio-myelitis except for a word or two. It seems fairly certain that dust plays an important part in the transmission of the latter disease. It is certainly both infectious and contagious and every case should be quar-

antined for at least three weeks, and should be treated promptly from the beginning.

Another point is the impermeability of the membrane to medicine administered by the mouth, hypodermically, or intravenously. If we are going to treat a disease that involves the meninges, brain or cord, the medication must be given subdurally or we will get no effect from it.

• • • • •

Next, renal troubles. Just two points. I have for many years been immensely interested in the question of so-called psychical or physiological albuminuria. In the past I have watched a small series of cases over periods of from ten to fifteen years, and I have concluded that this physiological, functional, psychical or adolescent albuminuria is not of very great importance pathologically. It is found under varying conditions and it is not constant. We may find it only upon arising in the morning, after a cold bath, after meals, or after violent exercise. It may be due to a lack of coagulability of the blood, or to some changes in the albumin of the serum, or the acidity, which influences coagulability. It may disappear after one or two doses of calcium lactate and then reappear.

A distinction should be made between physiological and pathological albuminuria. These cases are very troublesome in connection with life insurance examinations. It is a grievous blunder to reject an applicant with this form of albuminuria, in the absence of casts and other evidences of renal degeneration. But here let me emphasize the fact that casts, if hyaline, may be of very little significance. If we find either granular or epithelial casts, then, of course, the case belongs in the domain of pathological albuminuria. The absence of casts, however, does not exclude nephritis, as they are not always present in this condition. Therefore, repeated examinations of the urine should be made and no hasty conclusions drawn, or we may unjustly deprive a man of the benefits of life insurance.

There is a new test for renal function which, in my opinion is the best that has been brought forth. It is known as the phenolsulphonophthalein test. You are all, perhaps, familiar with the old indigo-carmin test that was in use several years ago. The test I speak of was devised by Geraghty and Rountree. A number of observers have been working with it and it seems to be of great value. The technic is easy. A small quantity of the phenolsulphonophthalein solution is injected into the lumbar or gluteal muscle and the urine immediately secured. If the kidneys are sound the fluid is quickly eliminated, and from 40 to 60 per cent. is obtained in the first hour, and a larger quantity in

the second hour. They have modified Hellige's colorimeter for measuring the quantity eliminated. This test, it seems to me, is of great value in surgical procedures involving the kidneys. It has also been shown that in chronic interstitial nephritis (which is one of the most fatal and most frequently overlooked forms of renal trouble), this test gives the best results. It sometimes does not give good results in chronic parenchymatous nephritis. It is also valuable in making a prognosis.

• • • • •

The next question that has interested me a great deal is with respect to rheumatism, arthritis and gout. If there is any class of disease in which knowledge has increased and wisdom has lagged, it is in this class. There has been a great deal of misuse of the word rheumatism. All authorities now agree that rheumatism should be called rheumatic fever, and should be regarded as an acute infectious disease, a growth or multiplication of certain kinds of streptococci, or other organisms of that kind. One point that I wish to emphasize is that we often confound this condition with arthritis which is not of the same character. I rule out of my pathology so-called chronic rheumatism and limit the term to the acute process. What a grievous mistake we have made in accepting the diagnosis of rheumatism as given so frequently by patients.

Another mistake we have made has been in not regarding it as an infectious condition, and believing it to be due to an acid condition of the blood. I know of no process, save perhaps, acute malaria, in which there is more rapid destruction of the blood cells than in rheumatism. Food here is necessary. Give these patients all the food they can properly digest and assimilate; otherwise we will do them harm. The next thing is to increase the dose of salicylic compounds, and combine it always with an alkali.

Chronic infections of the joints, hypertrophic and hypotrophic, we know less about. Some of these cases of so-called rheumatoid arthritis have no relation to either rheumatism or gout. Some infection may be the cause here; some belong under the head of tuberculous, and syphilitic; others under the head of nervous or trophic conditions. In these cases we want food, iron and arsenic, and, if there are contractions and adhesions, fibrolysin, then, hot-air, baths, etc.

Next, gout. I can count on my hand the number of cases of gout I have seen that fitted the description given in the English books, but I have had a number of cases of so-called American gout, and under this head should be included a great many conditions sometimes called rheumatism. Gout we know more about.

More articles have appeared on this subject in the German and English journals in 1911, than on any other except possibly salvarsan. We know that gout does depend upon an excess of uric acid in the body, in combination with soda-forming deposits about the cartilages, and so on. We know, further, that an excess of sodium in the tissues predisposes to the deposit of urate of sodium in the tissues. It must be that some idiosyncrasy determines this deposit; eating, drinking, and riotous living may do it. However, many persons lead God-fearing lives and still suffer from gout.

We make a grievous blunder when we attempt to treat gouty conditions with sodium salts; we simply add to the condition that already exists. If we are going to give any alkali, it should be potash lime salts, although muriatic acid would be far more logical and sensible than alkalies in gout.

The beneficial effects of certain waters are now recognized to be dependent upon radium, and the Germans are now using radium in water as the proper treatment for arthritis as well as gout in all its forms. They have a method of measuring the quantity given.

• • • • •

Next, tuberculosis, typhoid fever, and syphilis. There are three things that I wish to call attention to in connection with typhoid fever. First, the necessity of making earlier diagnosis and our culpability in not making early blood cultures. There are at least thirty-five thousand deaths from typhoid fever in the United States each year, and from forty to fifty thousand more are incapacitated, entailing a loss of about one hundred and fifty millions of dollars. We know all about its cause; we know how it is propagated, and we know that the normal habitat of this bacillus is in the human body. If we could just get the people to realize that the greatest danger is from human filth, and teach them to keep human filth out of human mouths, it would go a long ways toward eradicating this disease. The blood culture should be made. It is the consensus of opinion now, among the best hospital internists and laboratory men, that, with the modification of the bile culture media, diagnosis of typhoid fever in ninety per cent. of cases can be made inside of thirty hours. Every one of us must acknowledge that we have fallen far short of what we should have done in the way of making early diagnosis of typhoid fever. We hedge and halt, and wait for the second week with the typical spots. This test has been made a few times here, and we will be woefully behind if it is not made more often. It can be made by any competent bacteriologist. The Widal test, as a group test is of ever-

increasing value, but for individual cases I believe it is of diminishing value.

Next, typhoid fever carriers. There are two groups of these. One is simply a contact carrier, who may not have had the disease at all. He is not so dangerous. Another is one who has had the disease and still gives forth the organism from his body, either through the urine, from a suppurating joint, or by the feces. These carriers are accountable for many cases of typhoid fever that are otherwise inexplicable. Therefore, we have not done our duty by our typhoid fever patients if we do not have the urine and feces examined for the bacilli before we dismiss them as cured.

The treatment of these typhoid carriers is not satisfactory. We all use urotropin, which does a great deal of good, but in many cases it does not eradicate the bacilli nor does any other internal agent. The only report of any good derived from treatment that I have seen so far was from vaccine, and then only in a few cases.

The next point is in regard to immunizing doses of typhoid vaccine. We cannot put this aside any longer. Experiments in this country, in England and in Germany have put it beyond the domain of experimentation, and it is now an established fact. Some sixty thousand persons in the army of the United States have been immunized during the past three years. Of this number only twelve cases have been reported in which typhoid developed, with no deaths. Three injections are usually given, at intervals of ten days, the first containing five hundred millions of bacteria, the second one billion, and the third one billion. Typhoid immunization is now compulsory in all men enlisting in the United States army. How long the immunity lasts is a question. Some authorities claim that it continues for two to two and one-half years. Neither do we know how long the immunity conveyed by vaccination against small-pox lasts. Therefore, it may be well to repeat the immunizing dose.

Vaccine as a treatment of typhoid fever is not so well established. The number of cases that have been treated is small, but it looks promising.

Another point about typhoid fever is one of which I have frequently spoken, but I cannot forbear mentioning it again, that is, underfeeding. We have had impressed upon us so firmly the necessity for starving these patients that, although we now know a great deal more about foods and about the whole digestive process than we formerly did, it is hard to get away from the old superstition about feeding in typhoid. If you have kept up with recent works on digestion, you know that the carbohydrates play a very important part. Not only do we use them for their

high caloric power, but for far more than that. There is great waste in typhoid fever and, as the patient's digestive process is pretty good, this waste is largely due to mistreatment. Kendall has proven, beyond the peradventure of a doubt, that most bacteria, in the presence of carbohydrates, utilize them in preference to proteins. Bacterial toxins are associated with the breaking-down of proteins, and that is what makes the patient waste. Carbohydrates prevent, or check this process. Fermentation takes precedence over putrefaction. If you prevent putrefaction inside of a man you are doing him a service. Milk sugar is the natural carbohydrate in all milk sucking animals, and milk sugar is broken down in the intestinal wall just where the lesion is found. So, everything indicates that in typhoid fever, and all similar processes, such as dysentery, etc., lactose, or some similar compound, would be the ideal thing. Lactose does something more than this. It is a good diuretic without hurting the kidney; it protects the body nitrogen and the proteids of the food. It does not break down easily, prevents decomposition and is easily assimilated. I have been feeling my way along and increasing the dietary in typhoid for fifteen years. The juices of fruit I never withhold; home-made jellies that do not have seeds; milk, cream, lactose, softboiled eggs, soft toast and butter, stale bread and butter without any crust; beef, lamb and chicken broths, with rice, (which I prefer to other cereals), oatmeal or other cereals, gruels, custard, and ice-cream. I have sometimes had cause to regret not having fed a patient, but I have never had occasion to regret feeding. Instinct is sometimes a better guide than reason. What looks good to a patient, smells good, and makes him smack his mouth, will be better digested. These are three senses that can hardly lead you astray. One of the most important discoveries of Pawlow was that seeing things excited the flow of gastric juices. So, I let the patient chew—let him make his own beef juice. I will never forget the statement made to me by one patient, who said, "Doctor, I am tired of nonnishment; I want something to eat."

TUBERCULOSIS.

First, in regard to the test for the tubercle bacillus. I have seen a number of failures in the last year and I have myself had trouble by not applying the test properly. You want a good solution and a fresh solution, and when you make it do not be in too big a hurry. The tubercle bacillus is acid fast, alkali fast and alcohol fast. Next, the use of antiformin solution, a solution of caustic soda and hypochlorite of soda. Treat the sputum with this and allow it to settle, or centrifuge it, and in

many cases you will find the bacillus when it would be otherwise overlooked.

It is sometimes a delicate thing to make a statement for fear that it will be misunderstood. While I will readily admit that I see more cases of tuberculosis that have not been properly diagnosed, coming in as malaria, or liver trouble, or something else, than of other conditions which have been improperly diagnosed as tuberculosis, still I believe the tendency, in some quarters, is to make the diagnosis too early. I look upon tuberculosis as a very serious disease. It has become almost a fad to make early diagnosis, and I think we are creating, on the part of the public as well as among the profession, a phthisiophobia, and I am afraid there is going to be such a reaction as there was about appendectomy, after which it required a good deal of persuasion to get a man to consent to an operation for appendicitis.

Recent investigations on the blood and its role in bacterial diseases have completely changed our ideas on the diagnosis and treatment of pulmonary tuberculosis. Pulmonary tuberculosis, like all other bacterial diseases, manifests itself in two ways; (a) by physical signs due to local pathological changes in the lungs; (b) changes in the general health of the patient, due to absorption into the systemic circulation of bacterial products, produced at the primary focus. The latter is often of greater importance to the patient. A few crepitations matter little, provided constitutional disturbances are not pronounced. In other constitutional diseases, as diphtheria, typhoid, etc., we do not attach as much importance to the local manifestations as we do in tuberculosis. With the stethoscope we are liable to make numerous blunders. I cannot divest myself of the well-founded idea that we must take the man as a whole; that simply an adventitious sound, without other things considered in connection with it, is very often misleading. Tuberculosis, which is an acute infectious process, gives rise to certain well marked phenomena, and we should examine the patient for more than one thing. Would you undertake to say, from the amount of deposit on the throat, whether a case of diphtheria was going to die or get well? It is not a question of the local manifestations, but how much toxin has the patient absorbed, how much resistance will he put up; in other words, how is his general condition?

The most thought-producing and, to my mind, the most original contribution that has been made to this subject in the past year, is by Marcus Peterson, of the Brompton Hospital Sanatorium, who has published a book entitled "Autoinoculation in Tuberculosis." He emphasizes this fact; that it is the question of balance of the system that is of su-

preme importance in all bacterial diseases; that is, the ratio between the virulence of the invading organism and the specific resisting powers in the body against that particular organism. The work is original with him in many ways. He divides his cases into two classes; those with fever and those without fever. Those with fever (in the male about 99 degrees F. and in the female, 99 1-2) he "immobilizes," as he calls it; puts them to bed, has them fed, and does not allow them to do a thing, stopping the cough, stopping physical examinations and hammering on the chest, and even deep breathing, and all those things that we have used to bring out the signs. After the temperature has subsided, he begins the process of autoinoculation, with a combination of rest and exercise. We have had, seriatim, fresh air, feeding and rest; now it is fresh air, rest and food combined. Some time back it was a bottle of whiskey, cod-liver oil, and "Go West." I do not believe that fresh air is the Alpha and Omega of the treatment of tuberculosis, and I think that food sometimes does an immense amount of harm. I have seen patients who were fed until they were soft and flabby, but upon the slightest exertion they would drop down. Increased weight may not be an evidence of arrest of the disease, or even of benefit. We puff up his belly and puff up his face, and as soon as he gets out and tries to do any work at all, he loses his weight and goes back. By a milk and egg diet over-feeding the patient we are apt to do more harm than good.

Dr. Peterson tries to make the patient inoculate himself. He claims that the bacteria in the body generate a certain amount of toxin that will produce certain well-marked phenomena, and this is the process to which he applies the term autoinoculation. There comes a time when the patient gets better, and then, after another autoinoculation, he starts the patient on a series of exercises. He requires the patient to walk half a mile and then rest, and the effect upon the pulse, respiration and temperature is noted. The next stage is half a mile longer, and so on up to six miles. Whenever it causes too much reaction on the part of the patient, he puts him to bed. Next, after this series of exercises has been carried out, he puts the patient to carrying something. His idea is that if these patients are put at rest and do nothing, they get gloomy and despondent. We all like to feel that we are doing something. Therefore, he starts them with a bucket, holding six or eight pounds, and tells them to fill this bucket with gravel or sand and dump it on a certain heap. That is the first exercise. The second is the same, except that they are given a bucket holding twice as much. Next, the patient is given a small spade and told to pick

up some dirt and carry it from one place to another; then they are given a larger spade, and so on. By this means he gets a happy combination of "doing something" and exercise, and he claims that, if he can diminish the temperature and check the sputum, he is doing a great deal of good, and that many of these patients are able to work when they leave the Sanatorium.

CHEMOTHERAPY.

The goal of modern medicine is that (to me) hard-to-pronounce word, "specificity." The present era of progress in medical science is due to the recognition of the fundamental biological principle—specificity. Koch first gave it a definite standing in the declaration that every infectious disease is caused by a definite agent, found only in that specific disease; in other words, the causative organism is specific for that special disease. Von Behring discovered that, in response to invasion by bacteria, or other poisons, the body reacts by the production of substances which are specific for the products of these bacteria. Specificity is not confined to bacteria, but, as we now know, applies with equal force to certain proteins and fatty substances of the higher forms of animal and vegetable life, and may, to a certain degree, exist between the different tissues and fluids of the same individual. We know that the toxin of tetanus is fixed by nervous tissue, and this teaches us that there exist certain relations between cells and poisons as well as between blood serums and poisons.

The physician has two ways of preventing harm from these injurious agents; (1) reduce or remove the specific affinity of the cell for the toxic substance; or (2) render the noxa incapable of combining with the cell. The latter method has received the most attention, and under this head we have our valuable, though small number of, anti-serums and parasite drugs.

Ehrlich (to whom we owe most of our knowledge of aniline dyes), long prior to the discovery, while working on aniline dyes, developed the principle of specific chemical agents acting upon specific cells, and from this combination of physiologic chemistry with synthetic chemistry has developed the new branch of medical science, now so much talked about, called chemo-therapy, which is based entirely upon the principle that the chemical affinity of the drug shall be greater for the parasite or its poison than for the cells of the affected person. That is the fundamental basis—to find some chemical agent which will have an affinity for, or a special localized action upon the parasite or its poison, and at the same time not destroy the cell in which the poison may happen to be residing.

Ehrlich has proven that certain chemical substances have an affinity for, or are specifically attracted by, certain parasites, and these substances he styles parasitotropic. However, certain of these substances are capable of producing a deleterious effect upon the cell itself, and these he calls organotropic. Therefore, the problem was to strike a balance; in other words, to so change the chemical combination that its parasitotropic function would be greater than its organotropic function. "606" (which has set the world to talking more than anything else for a long time) was so styled because it was the result of the 606th experiment along this line.

An important point to remember, however, is that the experiments made by Ehrlich with these aniline dyes, modifying or changing their chemical combinations so as to develop their parasitotropic rather than their organotropic powers, were upon animals, and not upon human beings, and a certain condition in animals does not necessarily correspond to the same condition in human beings.

In this connection, Ehrlich has enunciated a dogma, which is one of the boldest in modern medicine, to the effect that we must find, if possible, some chemical agent of such potency that it will destroy at one dose, all the poison and entirely sterilize the body. "*Therapia sterilisans magna*" was Ehrlich's statement; find some chemical agent that will at one dose destroy all the parasites and do no injury to the body. That meant a cure.

Now, it won't hurt us to look back a little. It seems to me that this whole subject is illustrative of the old adage, "The first shall be last," etc. More than sixty years ago, long prior to the study of bacteriology, we knew that there were certain living organisms in the blood, but it has only been in the last ten years that medical scientists have been paying any attention to the animal forms—the protozoa, spirochetes, trypanozomes, etc. Ehrlich was the first to bring the attention of the medical profession to aniline dyes. He proved that methyl blue would stain the living cell, and out of that grew our modern bacteriology. But for the discovery of aniline dyes we would have had no bacteriology; the bacteria could not have been rendered visible by any other means. But, since this discovery, the medical profession has gone almost crazy on the subject of bacteriology. We know now that from the infectious diseases we get our serums and anti-toxins, but these organisms do not belong to the protozoa. The principal members of the protozoa are the malarial parasites, spirochetes and trypanozomes (and there are three or four others now—that of sleeping-sickness, and other animal parasites) and these do not seem to cause any reaction on the part of the body in the way of

developing antibodies, like the bacteria do. On the contrary, they seem to cause more trouble by being there, and weaken rather than exert any protective influence which may be present.

Sometimes instinct is a better guide than reason—sometimes empiricism outruns science. We knew an empirical remedy for malaria long before the malarial plasmodium was scientifically demonstrated. Chemotherapy has been developed more as the result of the discovery and recognition of the protozoa in the cause of disease, rather than bacteriology, and it seems to be coming into its own. The period prior to bacteriology and prior to chemotherapy had developed about the dominance of the cell—its structure and function, and when observers concerned themselves largely with postmortem material, leading away from physiological integrity, medical thought became pessimistic, and then therapeutic nihilism prevailed. Pathology gave us a better understanding than this, and a far more accurate diagnosis, but the study of specificity may add to our ability to cure and control disease.

I think that it is now pretty well accepted that salvarsan has come to stay. In a recent lecture by Ehrlich himself, before a German Society, he took up the various criticisms that have been made and makes the statement that when we consider that in the course of the past year, several hundred thousands of patients have been treated with salvarsan, the number of accidents is so small as to give no occasion for any serious objection.

Just a word in regard to the combination of trioxide and pentoxide of arsenic. In this combination it is trivalent, and the trioxide is unsaturated, and this is much more active than the pentoxide.

In conclusion I want to say a word about Noguchi's modification of the Wasserman test for syphilis. If employed with due care, it is often invaluable and decisive. He has cultivated the trypanozome and can demonstrate it very easily with the aid of dark ground illumination.

Noguchi has modified the Wasserman reaction, which is a difficult and dangerous thing to use unless one is qualified. It is the "man behind the gun." The Wasserman reaction is a good thing in early syphilis, and ought to be used. Noguchi's skin reaction is a very valuable one for later and hereditary syphilis. He has cultivated the disease through twenty-five generations, in rabbits and from the culture that he injects into the arm he gets induration, erythema, and then pustules.

However, no amount of laboratory technique will absolve the physician from the ordinary general precautions in making a diagnosis

Without laboratory aid, failure will often result, but elaborate pathology, unsupported by ordinary observation, is deprived of half its value. We should develop our powers of observation, so that the detective faculty may be of greater value when reinforced by making use of what advantages science can supply.

Just a prediction; I do not venture many of them, but I believe that the future of infectious diseases, so far as we are concerned, is going to resolve itself around three or four points. First, segregation of the infected individual or quarantine, if you choose to call it such, and, under that head, protection of the patient from the bites of disease-carrying insects. Right there, have we not made a mistake in the management of tuberculosis? The greatest problem of any, it seems to me, is the chronic tubercular subject. If you propagate the idea of early diagnosis of incipient cases, you will over-tax your very limited supply of sanatoria for that class of cases. The seeds scatter, and the most dangerous man is the chronic tubercular patient. Provision will have to be made—and in a short time, in my opinion—for admitting this class of cases to the regular hospitals. I believe there is great danger from the cases of chronic tuberculosis that now gain entrance to the general hospitals for some other trouble, surgical or otherwise. Next, I have seen some internes and nurses exhibit the most morbid fear of tuberculosis. The most valuable lesson taught to patients at the sanatoria is how to take care of themselves and how not to infect others.

The next point in regard to the management of infectious diseases would be to aid the body by giving certain sera. We must remember that sera are injected, not for their direct curative properties, but simply to stimulate the body to pour out certain antibodies, which will enable the system to deal with the infection. No man who is infected with any of these diseases gets well unless there is a response on the part of the body, causing protective substances to be thrown out. Next, the injection of certain vaccines, composed of dead or highly attenuated living bacteria, with the same end in view. Next, the use of certain chemotherapeutic agents intravenously to so fortify the body as to kill the parasites, or aid in destroying them.

DISCUSSION.

Carl Weidner, Sr.: I knew it would be a treat to hear Dr. Marvin to-night. He has given us a great many practical suggestions. His remarks in regard to typhoid fever, gout and rheumatism, were especially interesting. While I agree with his statements as to typhoid fever and rheumatism, I think that the diet in gout is

a very important point. It has been proven that in this condition we have a disturbance of the uricolytic ferment. We know that gout causes changes in the tissues about the joints, resulting in deposits of insoluble urates. We also know that certain foods, particularly those rich in nucleins, will produce the forerunners of uric acid. For this reason, I believe that, in gout, a diet rich in cells, such as sweetbread, liver, kidney, etc., must be excluded.

In the last few years, instead of giving alkalis in gout, I have been giving hydrochloric acid. We want to alkalize the tissues, but we do not want to alkalize the blood too much. All authors lay stress upon the beneficial effect upon toxin production which results from improvement of digestion; therefore, I give hydrochloric acid, first recommended by Falkenstein.

I would like to hear something about fibrolysin. I have never used it and I would like for some one who has to tell us something about it. I have several patients with sneaky joints upon whom I would like very much to use fibrolysin if it will dissolve some of these adhesions.

The suggestions made by Dr. Marvin in regard to feeding in typhoid fever are excellent, but I would like to utter a word of caution to some of the younger members. There is common-sense in everything. I am very skittish about feeding typhoid fever patients after they have had considerable hemorrhage. In such cases I withdraw practically all food, giving nothing but the smallest quantities necessary to sustain the body; also, ice and opium. I do not doubt that Dr. Marvin will sanction this treatment under such circumstances. We cannot lay down any hard and fast general rule in regard to feeding. However, as stated by the essayist, I think we have been underfeeding our typhoid fever patients as a rule.

It is hardly possible to properly discuss the subject of tuberculosis to-night, as the subject is such a wide one and the time is short. Dr. Marvin has given us some very excellent practical suggestions along this line, and I agree with practically everything he has said. As to early diagnosis, I believe that we are prone to look for it and fear its presence too much. Dr. Marvin struck the keynote when he said that we should not rely entirely upon the physical findings, but should take the patient's general condition into consideration. Whenever we cannot arrive at a positive conclusion in a suspicious case, we should employ the tuberculin test. I do not think we ought to send a single patient to a tuberculosis sanatorium without first having made positive diagnosis. When, after a careful examination of a patient, I am in doubt as to diagnosis, I put him down as a "suspect" and keep him under observation until I am satisfied as to the nature of the trouble. In a case of that kind, not far advanced, we cannot do any harm by making the tuberculin test. It is in the far advanced

eases that we may do harm by the injudicious use of the test. Therefore, in every case of this sort, if we are unable to find the tubercle bacillus in the sputum, the tuberculin test should be made. I have known—and so have you—of patients sent to tuberculosis sanatoria who had not tuberculosis. This is rather humiliating to the doctor.

One of the most interesting things to me is to note how the medical profession fluctuates, especially in regard to the treatment of tuberculosis. As has been indicated by the essayist, many contrary views are held with respect to exercise. Some advocate complete rest when there is fever, based upon the idea that the poisonous substances are increased by active exercise. On the other hand, some men advocate, even when the patient has fever, making him carry loads and do other kinds of work. One author has stated that where this plan was carried out he obtained just as good results as he did from rest. I do not approve of it myself. Whenever the patient has temperature, I try to reduce it by means of rest as well as by other means.

In regard to salvarsan, I think the time has passed for this agent to be criticised; still it is a new remedy. Ehrlich, in his latest report, cites many cases in which it was used without any bad results. However, every once in a while, in the literature, we see a report of a case in which optic neuritis is supposed to have resulted from the use of salvarsan. This ought to admonish us to be careful in its use.

Dunning S. Wilson: I certainly have enjoyed Dr. Marvin's masterly resume of recent advances along the line of internal medicine. I will pass over the various conditions mentioned by the essayist and confine my remarks to the question of tuberculosis.

First, I should like to emphasize what Dr. Marvin has said in regard to the diagnosis of tuberculosis. I think the more we see of tuberculosis, the more we realize that it is a general medical problem, and that, with a few exceptions, we never see an individual who is suffering from tuberculosis alone. I might mention, in passing, a case which Dr. Lucas and Dr. Abell saw with me a week or two ago, in which, if the diagnosis had been left entirely to Dr. Lucas, it would have been prolapse of the stomach; if it had been entirely left to Dr. Abell, it would have been movable kidney, and doubtless if it had been left entirely to me, it would have been tuberculosis. Microscopic examination of the sputum revealed tubercle bacilli. This case illustrates the fact that it is sometimes necessary to interrogate every organ of the body before we can arrive at a definite conclusion.

The more we see of tuberculosis the more we are impressed by the fact that, in the early stages, it is more commonly overlooked than it is diagnosed. I do not mean to say that a great many mistakes are not made. There is only one

class of men who never make mistakes, and they are the ones who never do anything.

In regard to the treatment recommended by Dr. Patterson as outlined by the essayist, this might be termed simply "Patterson's modification" of the general trend in the treatment of tuberculosis. The treatment now carried out in most sanatoria consists of fresh air, rest and food. In my opinion, if any one of these should take precedence over the others, I should put rest above fresh air and food. I contend that the reason so many tuberculous people live a great many years is because they rest during long periods. In the sanatoria, regular routes for walking are prescribed, and the patients are put in charge of nurses who see to it that these routes are followed. The patient is furnished with a slip of paper upon which is indicated the route he shall take, and a copy of this slip is given to the nurse. These routes are gradually increased in distance.

If there is one thing in Dr. Marvin's paper that stands out above all others, in connection with tuberculosis, it is that with reference to the dissemination of the disease by the chronic tuberculous patient. There was a time in the history of the City of Louisville and the State of Kentucky when it was necessary to establish sanatoria to demonstrate that persons of moderate means could be cured of tuberculosis in the climate of the Ohio Valley. That time, I think, has passed, and the time has arrived when our discussion should be devoted almost entirely to the question of chronic cases of tuberculosis. We rarely see a case of chronic tuberculosis in any family that we do not find from two to four other members of the same family afflicted with the disease. I hope the time is not far distant when the tubercular institutions of this part of the country will be so arranged that they will be able to take care of the chronic cases, and will be equipped with all the paraphernalia necessary to properly conduct a general hospital.

Herbert Bronner: I think Dr. Marvin has given us some very good points upon the subject of the diagnosis of pellagra. I have seen several cases that were at first thought to be pellagra but which, upon closer examination, proved to be a squamous eczema of the hand and forearm, or some form of dermatitis. Most of these cases were absolutely without gastrointestinal and mental symptoms.

Just a few words in regard to "606." I agree with the essayist that salvarsan is unquestionably here to stay, but we are still unable to say positively what is the ultimate effect of the drug upon the patient. I have given it for more than a year, both intramuscularly and intravenously, and I have reached the conclusion that we can not rely upon it alone. In both my private practice and hospital cases, I insist upon the patient's taking mercurial treatment afterwards, a procedure that is always carried out by Neisser. My

reason for doing this is because, after the use of salvarsan alone, I have seen a number of recurrences, both in my own practice and that of others, and an important feature of these recurrences is their severity and peculiar type. Take, for instance, a case in the City Hospital, in which I gave "606" last September. This patient had the initial lesion and the maculo-papular eruption. I gave him salvarsan, intravenously, and after six days the lesions had all healed. I explained to him the necessity for further treatment, which he refused, and in exactly two months he returned, with the most marked lesions I have ever seen. If this patient had received mercurial treatment and suffered a recurrence, it would have been of a mild form, but he had at least fifty deep tertiary lesions. Another case had been given "606" in Nashville, with no further treatment, and when I saw him, three months later, he had destruction of the soft palate. Therefore, when we do have a recurrence after the use of "606" it is of such severity as to make it appear that the spirochaetes had really been stimulated to renewed vigor by the drug. For that reason I never dismiss a patient without giving him the ordinary mercurial treatment in addition to "606."

I also agree with Dr. Marvin in all he has said in regard to vaccine therapy. The more we use it the more we like it.

J. Rowan Morrison: Dr. Marvin has given us a great many things to think about, and he has put them in such a way that I am sure they will be of great advantage to us.

One thing that especially interested me was the essayist's remarks about the different forms of arthritis. We have been too prone to class all these cases of arthritis under the head of rheumatism. As a matter of fact, acute articular rheumatism is not nearly so common as the histories given us by our patients would lead us to believe. It is necessary to make a very careful analysis of these cases in order to determine whether or not the trouble is infectious, or metabolic. From the standpoint of treatment it is very important to determine these points. If the trouble is of infectious origin, the vaccines may do good. If it is of trophic, metabolic, or gouty origin, plenty of food should be given but it should be reduced in purin bodies in the gouty form.

Dr. Marvin's remarks upon the subject of typhoid were extremely interesting. For a long time we have been underfeeding these patients. Dr. Ewing, of New York, has made a number of interesting experiments, showing that in many of these cases the pronounced toxic symptoms are due to the products of metabolism that are thrown off, the same as in eclampsia; in other words, it is the cell destruction that causes the symptoms and not the fight against the typhoid in the blood, and the way to overcome this is by giving these patients a proper amount of food.

In the excellent work done by Phillip Schaffer, he proved that he could keep up the nitrogenous equilibrium by giving carbohydrates. In typhoid fever food should be given for its effect and for its digestibility. Whenever the food begins to produce indigestion, or in cases of hemorrhage, it should be reduced. However, a great many typhoid patients can take care of reasonable quantities of food. It has been proven by many workers in physiological chemistry that 85 per cent. of carbohydrates and 80 per cent. of proteids can be taken up by the gut. Why not give food, if it does not produce indigestion, because it saves a lot of proteid material that in elimination in any other way will cause trouble. One of the most eminent authorities on this subject told me recently that he certainly believed in feeding typhoid patients, but he feared there was a tendency among some men to stuff patients full just to see what they could do with them—just as in tuberculous cases some men make a fad of feeding, until they have these patients with the belly-ache, and biliousness, and almost everything else. Of course, this is wrong. In typhoid food is needed, but it should be just sufficient to keep the equilibrium at rest, plus 25 per cent. to make up for the loss from toxemia and fever.

In regard to tuberculosis, rest is certainly essential in the presence of fever. Rest and fresh air reduces the temperature and stops the cough more quickly than anything else. If you rest and feed your patient, and give him fresh air, then the tubercle bacillus, to a certain extent, becomes inert—crawls into his hole, but if, on the first sunny day, the patient goes gallivanting around and overdoing himself, his fever returns, he has no resistance and he goes to the bottom of the pit again. As has been stated to-night, these patients should be trained to do work, but not to the point of producing high fever. When a little auto-infection is produced, it should be stopped. A moderate amount of exercise will produce a moderate amount of autolysis and a corresponding amount of vaccination, and this process gradually stimulates and increases the patient's resistance.

J. M. Morris: I am always glad to have the opportunity of hearing Dr. Marvin. I have no hesitancy in saying that the essayist attempted to cover too much ground in one paper. It was impossible to carry them all from beginning to end, because he dealt with too many different phases of medicine.

The essayist referred to tuberculin as a diagnostic measure, which was good, but I was hopeful that he would refer to it as a therapeutic agent. I want to go on record as a firm believer in tuberculin in the treatment of tuberculosis. I think it is a measure that is worth more to us than any other and one that, properly given, will always produce results. Especially do I believe this to be true in renal tuberculosis. My observation has been that, in this condition, tubercu-

lin properly given from the beginning, as early as the disease can be diagnosed, is a therapeutic measure that stands above anything else. Also, in pulmonary or any other form of tuberculosis, the value of tuberculin should not be overlooked. There is not one of the larger institutions for the treatment of tuberculosis where tuberculin is not looked upon as a therapeutic measure of high value.

Dr. Marvin also touched upon vaccine therapy. I also wish to go upon record as believing that the vaccines constitute the most valuable therapeutic measures that we have at our hand, especially in infections of the genito-urinary tract. I do not believe that stock vaccines are of any great value in many instances, because they do not fully cover the field of infection, but autogenous vaccines, properly made (and we have men here who are able to make them properly) are, I believe, of the greatest value, especially in renal infections. We know, for instance, that colon bacillus infections that have failed to respond to any other form of treatment, have been cured by the use of an autogenous vaccine.

The essayist stated that tuberculous patients were formerly sent West for treatment for tuberculosis. I want to say that this is still practiced with very good results. I do not believe that we can get the same results here that we can in higher and dryer climates. Any man who will take the time and trouble to investigate the statistics relative to the climatic treatment of tuberculosis, cannot come to any other conclusion than that certain climates are much more favorable than others for the treatment of this condition.

In regard to exercise in tuberculosis, some of these patients spend a few months in the Rocky Mountains and appear to be benefited by it. While on a visit to the Rocky Mountains, I had pointed out to me a trail up the mountain side, which was called Isaac's Trail. It took its name from a Chicago man who went there, far advanced in tuberculosis, and essayed to ascend the mountain. During the first few days he could only go about a hundred feet, then two hundred, then four hundred, and so on until, in the course of a few weeks, he was able to reach the top of one of the highest peaks in the Rocky Mountains. After that he ascended and descended so often that he wore a trail, which to this day is called Isaac's Trail.

J. B. Marvin, (Closing): In closing, I wish to simply refer to one or two questions that have been asked.

The point that I wanted to bring out about tuberculosis was this: That a man may have within himself the seeds of Death we know full well, but perhaps he may also have within himself the seeds of life, and if we can bring about a proper balance we may save him. The next point was, I do not see the benefit of having a machine that is so wrecked and so poor that one can do nothing in

this world except to sit in a chair and drink milk.

In regard to tuberculin, like most of us I speak of it with a great deal of diffidence. I have been very slow to use it. I believe I can claim to have been the pioneer in the use of Koch's original tuberculin here, and I have been feeling guilty ever since because I rushed in and used large doses, and may have killed some of these patients.

If you will read a recent article by Lawrason Brown (than whom I do not believe there is a better man in the United States) you will see that he is very conservative in regard to the use of tuberculin. I think we should make a distinction between the reaction from tuberculin, and auto-intoxication, or inoculation. I am afraid that sometimes, in a case of tuberculosis that has had sanitarium treatment and is doing well, if we inject tuberculin we may wake up something that will do more harm than good. Don't be in too big a hurry to use vaccines. Too large doses, too frequently repeated, will do much more harm than good. I have seen marvelous results from a single injection of serum in cases that I had expected to go under, and in which I am satisfied that further injections would have done harm. Feel your way. The modern terminology of medicine is an unknown tongue to the man of medicine of five or ten years ago, and we will do well to familiarize ourselves with it, and to note the trouble that may come from too frequent or too liberal use of the vaccines. The day of intravenous medication is at hand. I have never felt so much like getting out my old lancet and learning how to use it again as I do now. In making these injections we must learn how to slip the needle under the vein easily and fixing it.

A word about salvarsan. Hardly any one believes that, in ordinary human syphilis, one dose will do the work, but we all believe that it will do good. I was taught to do nothing for several months and await developments. Now we know that the earlier we begin on syphilis, the better chance the patient has. Ehrlich says that most of the trouble from salvarsan is due to faulty technique. Unless you have absolutely sterile water, you will get some very bad results from these injections. Another point is this: I do no surgery, but I have been astonished sometimes by the effect upon patients of the mistake on the part of the operator in allowing the subject to see all of the paraphernalia intended to be used in the operation. The shock, or psychic effect, produced by the sight of the instruments, just as you are getting ready to open a vein, will have a very bad effect upon some of these cases.

I know nothing that will produce optic neuritis more quickly than arsenic, unless it is wood alcohol.

A SHORT TALK ON ANESTHETICS.

By W. A. ONDERDONK, Louisville.

In this short talk on anesthetics, the essayist makes no claim for originality, the object of this paper being to awaken more general interest in the subject of anesthetics and the administration of same.

When, in 1847, Sir James Y. Simpson gave to the medical world chloroform, it was thought that the ideal anesthetic agent had been found. Chloroform has a sweetish, pleasant odor; therefore not disagreeable to the patient; is in compact form, therefore easily carried; produces a sleep-like state, with motor and sensory nerves sufficiently dulled to permit of any surgical procedure; there is little post-anesthetic nausea.

The confidence in this agent was short-lived; reports of deaths, which could be traced directly to this anesthetic, were early reported.

To the British Anesthetic Committee we are indebted for the bulk of our scientific knowledge of this drug, though America has not been lacking in this work, and the American physicians early gave up chloroform as the routine anesthetic and adopted those which had proven themselves less dangerous.

Chloroform is taken up mainly by the red blood corpuscles, and it is said, by Moore and Roaf, to form unstable compounds with the protoplasm of the blood and tissues. It is a cardiac depressor, acting upon the inhibitory mechanism of the heart, and producing syncope from dilatation of the capillaries through the vasomotor system. Chloroform inhibits the heart muscle also through the coronary arteries, as is shown by experiments of Sherrington and Sowton.

The prolonged action of chloroform-laden blood results in paralysis of the respiratory center. Failure of respiration has usually been assigned as the first danger of chloroform, and, second, failure of the heart.

There has been much controversy over the point as to whether fatal syncope was due to respiratory or cardiac paralysis. Hewett thinks that the modern consensus of opinion establishes heart paralysis as the chief event. In all cases there is a considerable fall in the blood pressure.

It is recognized as a fact that most deaths from chloroform occur in the early stage of the anesthesia, the stage of excitement. During the struggles of the patient he holds his breath, the pulmonary blood pressure is raised and the venous system is congested. If the anesthetist continues the administration in an effort to "get the patient under," suddenly a deep inspiration carries a densely concentrated vapor to the lungs. Blood laden with chloroform enters the coronary arteries and causes paralysis of the heart

muscle. Most of the primary accidents with chloroform are due to over-dosage. In the administration of chloroform, the Edinburg method of "plenty of chloroform with plenty of air," is safe. Snow, in 1849, advised against using more than 2 per cent chloroform vapor, claiming that a higher percentage was extremely dangerous.

Bevan and Favill have shown that cases of late death after operation under chloroform, formerly thought to be from shock, sepsis, fat embolism, etc., and coming on in from ten to one hundred and fifty hours, with vomiting, restlessness, delirium, convulsions, coma, cyanosis, or icterus, are due to hepatic toxemia. This is caused by the destruction, by chloroform, of the liver cells especially, as well as other structures, and the toxemia is in proportion to the quantity of chloroform used. Only lately, P. W. Monroe, of the City of Mexico, reports in the *Jour. A. M. A.*, six fatal cases of late chloroform poisoning occurring there within fifteen months.

Hamberger and Ewing, in 1908, found that chloroform reduced the hemoglobin in the blood and, therefore, produced anemia. It also produces a decrease in the coagulation time, which is, however, not so marked as that of ether.

SULPHURIC ETHER, OR ETHER, AS IT IS GENERALLY KNOWN.

The exhilarating and anesthetic properties of this agent had long been commonly known, but it was not until Long, of Georgia, in 1842, used it in surgery, that the profession awakened to its value in producing surgical anesthesia, and by 1847 it was in use throughout the civilized world, and is to-day more generally used than any other agent to produce surgical narcosis.

Ether is a clear, colorless liquid; boiling point about 95 degrees Fahrenheit. This low boiling point is one reason why it has not proven satisfactory in the tropics. It is volatile and inflammable, and, when its vapor is mixed with air, explosive; has a sweetish taste and odor; irritant, producing a sensation of cold, and, if sprayed on, the surface may be frozen. If care is not taken the face may be frozen when the open mask is used.

Quoting from Hewett: "Two main characteristics of ether are: firstly, that it is one of the most energetic stimulants known, not only to the circulatory, but to the respiratory, nervous and glandular systems of the organism; that its vapor is, as compared to that of other anesthetics, more irritating to the respiratory passages, so that mucus is often freely secreted."

Ether affects the respiration in two ways. Owing to the irritation of the mucous membranes of the throat and nose, there is a reflex

slowing, and occasionally a temporary inhibition of respiration. This may be accompanied by a spasm of the glottis. Such a disturbance need not be caused if the anesthetic be given slowly. Soon, if the anesthetic is forced, and gradually, when it is given carefully, the nerves of the throat become numb and the respiration then becomes regular and slower. The struggling, gasping respiration can generally be avoided by proper administration of the anesthetic.

The effect of ether on the circulation is modified by its effect on the respiration; the heart beats quickly when respiration is disturbed, and if the respiration is regular the heart is regular; if there is much nervous excitement the heart shows excitement and beats rapidly. The circulation is thus influenced by both the nervous and respiratory systems. When the surgical degree is reached the heart slows and the pulse becomes full and regular unless shock occurs.

In normal conditions, ether usually gives notice of danger by impairment of respiration. In too profound anesthesia or in insufficient anesthesia, when sudden pain may cause pneumogastric inhibition, or in diseased heart conditions, with disease of the coronary arteries, the heart may suddenly cease and death may occur.

Ether gradually produces vasomotor paralysis; the more prolonged the anesthetic and the more anesthesia used, the more vasomotor weakness.

Graham, Stewart, and others, have found that following ether the opsonic index is greatly reduced, and they think this due to the fat-solvent properties of ether, whereby the destruction of bacteria by phagocytes is greatly reduced, and the patient is more susceptible to pneumonia and other infectious diseases.

In the summary of Hamberger and Ewing, of their findings of the effect of ether on the blood, we find, (a) hemoglobin slightly reduced; (b) term of coagulation decreased, most pronounced from 7th to 10th day, and these conditions can be demonstrated after as short an anesthesia as fifteen minutes, and must surely retard convalescence.

Ether is thought to be irritant to the normal kidney, and may cause an albuminuria. It is, however, dangerously irritant when there is an acute inflammatory condition of the kidney and may cause serious trouble.

Ether is about six times as safe as chloroform.

NITROUS OXIDE.

This gas, discovered by Priestly in 1772, and introduced to the medical profession by Wells, in 1844 as an agent capable of producing surgical anesthesia, has until lately remained the least appreciated of all the agents

at our command capable of producing general surgical narcosis. The dentists have long used this agent for the extraction of teeth and other minor work, and to them we are indebted for most of our knowledge. Their clinical work, done without previous preparation of patients, is little short of marvelous. Few casualties have been reported. Of late years, with improved methods of administration, pure gas, and better knowledge of the action of this agent, the medical profession is gradually accepting it for major surgery, and nitrous oxide is surely coming into its own.

Nitrous oxide is a clear, colorless gas, with a slightly sweetish taste, and is produced from ammonium nitrate. We get it in steel tanks under a pressure of about 750 pounds to the square inch. This bulky package is one of the most disagreeable features of its use.

The physiological action of nitrous oxide has been variously explained. Its action, as first taught, was that the gas, after entering the tissues, split up into nitrogen and oxygen, producing hyperoxidation. The fallacy of this theory is proven by nitrous oxide being exhaled in its original state. Another and more dangerous view was that nitrous oxide exercised no specific action, but mechanically displaced oxygen from the lungs, and so led to tissue asphyxia. This theory is easily refuted, for it has been found that nitrous oxide exerts a greater anesthetic power in the presence of sufficient oxygen to prevent cyanosis.

The more rational, and the now more generally accepted theory of its action, was first advanced by Paul Berth, and has been proven by later investigators. This theory is that nitrous oxide is a true anesthetic, which, upon being inhaled into the lungs, is taken up by the blood and lymph; thence to the nerves, producing a temporary cessation of their function, the respiratory and cardiac centers being the last to succumb.

Seeds, if sprouting, cease to develop when placed in an atmosphere of this gas, but resume their growth when again placed in air, or when oxygen is admitted to them.

To Adams, of Chicago, belongs the credit of discovering that, by the addition of the proper amount of oxygen, the asphyxial symptoms of nitrous oxide are prevented without destroying its anesthetic properties.

The question is often asked: "Why cannot air be used to overcome this cyanosis instead of oxygen?" Because atmospheric air contains (approximately) 79 per cent nitrogen, and (approximately) 20 per cent oxygen. Therefore, in using air with nitrous oxide, you can readily see that a great quantity of nitrogen is admitted and only a small proportion of oxygen, when oxygen alone is needed, and Van Arsdale, Kemp, Paul Berth, have shown that 70 per cent. of nitrous oxide

is the lowest possible percentage with which narcosis can be produced.

The Anesthetic Commission of the American Medical Association, reported at its session in St. Louis, as follows: "As a routine anesthetic, nitrous oxid has a peculiar value," Dr. Frederick Hewett, of London, says: "There is no form of anesthesia at present known, which is so devoid of danger as that resulting from nitrous oxid when administered with a sufficient percentage of oxygen to prevent all asphyxial complications." Thomas, of Philadelphia, has administered it 271,940 times, (*Jour. A. M. A.*, Nov. 7, 1908, p. 1576), with only one death, which occurred five hours after the administration and was due to apoplexy. Colburn, of New York, has given it in an operation lasting over four hours.

With nitrous oxid, complete anesthesia occurs in from fifty to sixty seconds; and lasts from thirty to sixty seconds; with oxygen this period of anesthesia can be prolonged indefinitely.

The anesthetic is lighter than that produced by ether or chloroform. With oxygen it resembles normal sleep, with complete relaxation, and is seldom followed by nausea.

According to Kemp, there is no direct action on the heart or vasomotor centers. Hamburger and Ewing found no lasting effect on the blood.

Respiration is primarily stimulated, but, unless oxygen or air is admitted, it is secondarily depressed and finally ceases from muscular spasm.

ADVANTAGES OF THE USE OF N O WITH O.

1. Safety at time of its administration, and later in absence of circulatory, respiratory or nephritic complications, or acid intoxication.

2. Rapidity.

3. Comfort of patient, both in induction and absence of post-anesthetic complications.

DISADVANTAGES.

1. Cost. This is somewhat greater than in the use of chloroform or ether.

2. Necessity of skill in administration.

In comparing the death rates of these anesthetic agents, we find, according to the best obtainable statistics:

Chloroform	1-3,162
Ether	1-16,302
Nitrous Oxid.	Hewett found only 17 deaths.

The principal contraindications for the use of N O are:

1. Restricted air passages, goiters, enlarged lymph glands, enlarged tonsils and adenoids.

2. Dilated, weak heart, with or without valvular troubles.

Nitrous oxid should be the anesthetic of preference for those patients who have had unpleasant experiences with other anesthetics, those suffering with grave septic conditions calling for surgical operations, and the tuberculous patients.

The next in safety to nitrous oxid and oxygen, for a general anesthesia, is the nitrous oxid-oxygen-ether sequence. In this method the patient is first anesthetized with nitrous oxid; then use sufficient oxygen with the nitrous oxid to prevent cyanosis, and, as soon as consciousness is lost, begin with ether, giving with the gas in gradually increasing amount, and when complete ether narcosis is obtained, (four to eight minutes), discontinue the nitrous oxid and oxygen and continue the ether with air.

The advantages of this method are:

1. By the elimination of the stage of excitement and the smaller quantity of ether inhaled, there is greater safety than with ether alone.

2. By mixing oxygen with the nitrous oxid, a longer narcosis can be maintained than by the use of nitrous oxid alone, thus permitting ether to be given in a slow, graduating method.

3. Induction period more pleasant for patient.

4. By first establishing narcosis with nitrous oxid and oxygen, then gradually using ether, the excessive secretion of mucus can usually be avoided. The swallowing of the ether-laden mucus adds greatly to the post-anesthetic nausea.

5. Saving of time, as patient is unconscious in about 50 seconds and thoroughly under ether in from 4 to 8 minutes.

6. By using the Cunningham, Teter or the last Gatch apparatus there is less liability of pneumonia or other bronchitis, on account of inhalations being warmed and thoroughly mixed ether vapors only being inhaled by the patient.

Joss found that ether cools the air inhaled through the mask so that it averages 33 degrees F. below the temperature of the room, and that the difference may be even 44 degrees, and claims that the cilia of the ciliary epithelium, lining the air passages, are affected by the variation of temperatures; that the ciliary movement is entirely arrested at the freezing point. Infectious material is thus liable to find its way more readily into the finer passages.

Turnbull, in reviewing deaths from ether, says: "It appears that most deaths from ether occur during the stage of excitement, or before complete narcosis is established."

No deaths have been reported from the use of this method.

The time was, but is now past, when all that

was expected of an anesthetist, was for him to get a patient under an anesthesia keep him quiet and then get him off the table alive.

But now with our more advanced knowledge of the therapeutic action and sequela of these agents, his duties have expanded.

It is now expected that by the careful selection of the agent or agents, and the scientific method of administration he should bring about a pleasant and tranquil state of narcosis, to use as small amount of the anesthesia as is consistent and when patient is taken off the table, to leave him not only alive, but, as far as the anaesthetic is concerned, in a better condition for convalescence.

DISCUSSION.

J. W. Heim: About the last thing that I heard the essayist say, was that no deaths had been reported from nitrous oxid and oxygen anesthesia, but deaths have been reported from all forms of anesthesia. I have had one death to occur on the table, while the patient was under nitrous oxid and oxygen. Of course, I would not say that death was due to the anesthetic, because we cannot say positively that any of these deaths are due to the anesthetic employed.

I arrived late and did not hear all of the paper, but, in the main, I agree with the essayist in what he has said.

One point that I want to emphasize is that nitrous oxid and oxygen is by far the best means of inducing anesthesia in every case, unless perhaps in the case of very young infants. Anesthesia is so rapidly produced, and such a small amount is required that, if we are not very careful, we may get the child too far under. Furthermore, if the child is very small, the cone does not fit the face. However, in practically every case, if we are going to give ether, it is much safer to begin the anesthetic with nitrous oxid. The greatest danger from any anesthetic is in the beginning and by using nitrous oxid we get the safest anesthetic at the most dangerous time. We also have less nausea when we begin with nitrous oxid. The patient does not swallow the ether-halen mucus because the reflexes are abolished before the ether is begun.

I have enjoyed the paper very much indeed.

E. L. Henderson: I wish to congratulate the essayist upon his excellent paper; he has left very little to be said in discussion.

I wish to endorse what Dr. Onderdonk and Dr. Heim have said in regard to inducing narcosis with nitrous oxid and oxygen, especially where it is intended to use ether. In my opinion, it is by far the safest method of inducing anesthesia. If a little atropin be given prior to the anesthetic, and narcosis induced by means of nitrous oxid, post-operative nausea will be lessened to at least forty per cent.

Another point I wish to mention is the possible danger from the use of nitrous oxid. So much

has recently been said in regard to the safety of this form of anesthesia that it would lead one to believe that there is practically no danger, whereas, I believe that, in the hands of an inexperienced man, nitrous oxid and oxygen is really more dangerous than ether or chloroform. However, in the hands of experienced men, I believe it is the safest anesthetic we have to-day. The essayist stated, I believe, that no deaths had been reported from the use of nitrous oxid. On the contrary, during the past year quite a number of deaths have been reported from this anesthetic, but they have all been in the hands of inexperienced men.

Ben Carlos Frazier: Dr. Henderson has just brought out a point that is not appreciated by many of us as it ought to be. I think inexperienced men are the ones who lose patients, from ether, chloroform, or any other anesthetic. It has been my observation during the past eighteen years that most of the patients that have been lost from chloroform in this city, have been by men who have not had experience in giving any anesthetic. I have never given nitrous oxid, and I would be afraid to give it because I have had no experience along that line.

J. Garland Sherrill: This subject is interesting to all of us, and especially to the men doing operative work. My observation has been that the choice of an anesthetic is determined largely by the experience of the man who is giving it, and, secondly, by the condition of the patient who is to receive the anesthetic. Certain forms of anesthesia are contraindicated in certain conditions. In old patients, or in cases where there is bronchial irritation making it inadvisable to have the amount of secretion that is caused by ether, chloroform is undoubtedly the best anesthetic, while in certain other conditions, ether is unquestionably to be preferred.

Up to ten years ago I was a strong advocate of chloroform, having seen it used more often than ether throughout the various clinics of the world, some men not hesitating to give it in the presence of heart murmurs, and under practically all conditions. I have seen it administered in a number of cases in which ether advocates had refused to give ether. Therefore, I say that in giving any anesthetic, we must have a man who is familiar with what he is giving and the anesthetic must be suited to the condition of the patient. The first dose of chloroform may kill your patient by causing paralysis of the heart, or death may occur later from an overdose of chloroform, resulting in paralysis of the respiration. Therefore, chloroform should be administered very gradually.

I must confess that I have known of deaths from chloroform in this city in the hands of very competent men. I have also known of deaths from ether under similar circumstances, and I believe deaths will occur, no matter who is giving the anesthetic. Therefore, I do not think we

should attribute all deaths from this cause to incompetency on the part of the anesthetist. I have seen two patients die under ether and one under chloroform. These cases were all in the City Hospital and not in my private practice. In the chloroform case, the patient was very seriously handicapped. He had a collapsed lung prior to the administration of the anesthetic. We all agreed that it would be pretty risky to anesthetize him, but he was in such condition that it was deemed advisable to attempt it. Whether he died from the anesthesia alone, or from a combination of the collapsed lung and the anesthesia, I do not know. The chest was immediately opened and the heart manipulated, without avail.

I recall a death which occurred from nitrous oxid and oxygen anesthesia in the office of a dentist of this city. The history obtained later showed that this patient had had a diphtheria some weeks before, which at the time was thought to be tonsillitis. I was in the adjoining office and was called in to see the patient after she was dead. I do not think this death could be ascribed to incompetence, because the anesthetic was administered by a man who has given a large number of nitrous oxid anesthetics as formerly given by dentists.

The greatest danger in giving an anesthetic is in allowing the patient to come out and then put him under again. The reason for this is apparent. Every time the patient comes out and is put under again, he is given a little more shock. I don't want a man who is afraid to completely anesthetize the patient; I want a man who will put the patient under and keep him under until the operation is completed. I believe that, with any anesthetic, the best results are obtained by keeping the patient under the surgical degree of anesthesia.

J. Hunter Peak: I know very little about giving anesthetics, although I have had a great many of them given for me. Dr. Onderdonk has given several hundred anesthetics for me during the past eighteen months, and we have not had a death from anesthesia in that time. Only once has any condition arisen which has given us any trouble. This was a patient who gave a history of some previous nephritic trouble, but at the time of operation, which was a perineorrhaphy, urinalysis was absolutely negative. On the second or third day following the administration of ether, the patient developed an anuria and we had a hard time in getting the urine started again. Whether the administration of ether was responsible for this trouble, by starting up the old nephritis and producing an acute condition, I am unable to say positively, but I believe it was, because, following this, the woman had considerable albuminuria which afterwards cleared up, and she is now in good health.

Prior to the adoption of the present method of warming the ether vapor before it is administered, I saw three deaths from ether pneumonia,

from 72 hours to 6 days following the anesthesia, but we do not have this trouble now. I have also seen one death from chloroform anesthesia. This patient was in very poor condition for anesthesia, and just about the time the first incision was made, he died. Apparently, death was due to paralysis of the heart. If, when we give chloroform anesthesia, we can get the patient off the table and into bed in good condition, the subsequent complications are less than from ether. However, under the present method of warming the ether vapor, I have not seen a single bad result from it.

In regard to nitrous oxid and oxygen, I am glad to say that I have confidence in the man who gives anesthetics for me, and I allow him to give whatever he thinks is best suited to the individual case. The anesthetist should have an opportunity to see the patient the day before operation, and examine the heart, lungs, condition of the kidneys, etc. He should make these examinations himself, so as to familiarize himself with the exact condition of the patient, and he should then be the judge as to what form of anesthesia should be administered. I prefer an anesthetist who is competent to administer more than one form of anesthesia. If a man is going to make a practice of administering anesthetics, he should be able to meet conditions as they arise, and to give any kind of anesthesia that may be indicated. We are all called upon to face conditions that are ordinarily unlooked for, and the same thing may reasonably be expected of the anesthetist.

John B. Richland, Jr.: There are just two points I wish to mention. Dr. Sherrill mentioned the danger of allowing the patient to repeatedly go under and come out. Ninety-nine times out of a hundred this is the surgeon's fault, because he will not wait until the anesthetist can produce the surgical degree of anesthesia.

The second point is the question of the anesthetist's fee. It seems to me that it is asking a great deal of a man who trains himself as an anesthetist should be trained, to expect him to be satisfied with a fee of five dollars for giving an anesthetic in a case in which the surgeon's fee is from two hundred and fifty to five hundred dollars. The anesthetist's fee should be based, as the surgeon's is, upon the patient's ability to pay.

W. A. Onderdonk, (Closing): I wish to thank the gentlemen for their discussion of the paper.

Answering one of the speakers, I will say that the statement made in the paper was that to my knowledge no deaths had been reported from nitrous-oxid-oxygen-ether anesthesia. I also stated in the paper that the anesthetist, is, and should be, expected to exercise great discretion in his choice of an anesthetic in any particular case.

THE TREATMENT OF NEPHROPTOSIS.

By J. HUNTER PEAK, Louisville.

There has been so much written upon the subject of movable kidney in the past few years, that it would be impossible, in a twenty-minute paper, to take up the entire subject in detail; hence it is my desire to limit this short essay to the consideration of the treatment of movable kidney, in order that a free discussion of this phase of the subject may be elicited.

To be perfectly fair, I want to give a brief resume of the subject as contained in the published views of writers on both internal medicine and surgery.

Tyson, in the fourth edition of his work, page 749, says: "As may be inferred, many cases of movable kidney require no treatment. In a few instances, the symptoms are relieved by improving the general health; in others the patient is comfortable while lying on the back, and such comfort may continue for a time after rising. When decided symptoms attributable to the kidney are found, surgical treatment for fixation is alone of permanent value, and this sometimes fails. The use of pads and supports has never proved successful in my cases. Dr. A. Symons Eacles, however, has reported five cases of nephroptosis treated by an abdominal belt and pad, massage and exercise, with relief of all symptoms."

Dr. William Gilmore Thompson, in his second edition, page 710, says: "My experience with pads and bandages is that they do more harm than good. As the symptoms are intermittent, disappearing for long intervals, I usually advise patients to bear with them, seeking only to avoid the strain of jarring or jolting, or any excessive fatigue. Intractable cases may be relieved by sewing the kidney capsule to the abdominal wall, but it may break loose again, and the operation, while sometimes curative, and usually attended by little or no risk, may fail of permanent relief. It is scarcely to be recommended for kidneys which are merely 'palpable' and not 'floating'. Rest upon the back for three or four days sometimes gives relief for a considerably longer period. The general treatment is that of neurasthenia and nervous dyspepsia, conditions most often associated with movable kidney; and much can be done by building up the general health and strength and improving the muscular tone."

G. Dieulafoy, in his fifteenth edition, volume II, page 1197, says: "The medical treatment of movable kidney has as its object the maintenance of the organ in position by appropriate bandages. Massage may give good results. Nephropepy is often necessary. This operation consists in provoking adhes-

ions between the kidney and the abdominal wall.

Tuffier's figures read: In 163 cases: Perfect cures, 86; lasting improvement, 25; satisfactory results, 24; temporary improvement, 8; failures, 20.

"In several cases the ectopia and co-existing nephritis have been cured simultaneously by nephropepy."

Alexander Bryan Johnson, in his second edition of "Surgical Diagnosis," Volume II, page 402, says: "In the somewhat rare cases in which spontaneous reduction does not soon occur, the attempt may be made to rotate the kidney bimannually into its normal position; this effort has been successful, in a few cases, in giving temporary relief. Prolonged rest in bed is a very valuable, and usually temporarily successful, mode of treatment. Elevation of the foot of the bed, and even a partial Trendelenburg position, may also be tried. In the large majority of cases of movable kidney, its fixation in the loin by suture is a certainly curative procedure."

Sir Frederick Treves, in his "Operative Surgery," Volume I, Page 535, says: "The subject of nephroptosis, or movable kidney, has of late caused much discussion. On the one side are those who say that the condition is found in one woman out of every five, that it rarely causes trouble, and that it is but an incident in a general disorder, and that any treatment, if required, should consist in the use of supporting apparatus rather than an operation; on the other side are those who affirm that floating kidney is the cause of considerable trouble, both local and general, that it usually requires an operation, which operation will relieve all symptoms in three fourths of all cases. The truth must lie somewhere between these two extremes."

Now, since the profession recognizes the existence of such a condition as movable kidney, and nearly all claim that from seventy-five to eighty per cent. can be relieved by operation. I do not see any valid reason why movable kidney should not always be placed in the category of surgical conditions. Since we now know the concomitant symptomatology of this very prevalent condition, I do not understand why every case should not be operated upon, just the same as any other surgical condition of equal gravity. The claim that many cases do not cause any trouble, I do not believe can be substantiated. Particularly is this true if the kidney is freely movable. Then why should a physician subject his patient to the trouble and inconvenience of wearing belts, adhesive dressings, and taking long rests in bed, from which nothing but temporary relief can be expected. If admitted that, for a while, this condition may not cause trouble, is it not true that it will do so,

sooner or later? Or, may it not begin to be troublesome under some exciting cause, possibly as the result of an accident of some kind occurring during the ordinary routine duties of life? Then, too, a fibroid uterus may not cause trouble for many years, but please show me the physician of to-day who will contend that, in the presence of such a condition, the uterus should not be removed, barring some physical contraindication to operation. We are told that, in some cases, operation will fail of permanent relief, yet the same men admit a very large percentage of cures. Again, I say that a few operations for hernia are failures; yet we never hear any one say that, because of this fact, a patient suffering from hernia should not be operated upon. Therefore, I claim that nephropexies, in the hands of skilful operators of to-day, are just about as successful as herniotomies; yet the technique of herniotomy is as old as surgery, while that of nephropexy is as yet almost in its infancy. For one to say that this operation has not been successful in his hands is to admit that his technique is faulty.

In a discussion of the treatment of movable kidney, it is not my intention to go into the operative technique of nephropexy; this can be found in all of the best works on operative surgery. However, I desire to give you some of the valuable points that I have learned by experience.

In my judgment, the only treatment, other than surgical procedure, can be summed up in a few words; namely, proper attention to the general health, with a view of increasing the muscular tone, particularly of the abdominal muscles. This may be accomplished by hygienic living, with due regard to passive and active exercise, such as massage of the abdominal muscles, which should always be done by stroking from below upward, with the patient in a reclining position with the hips higher than the shoulders, together with such other calisthenics as will develop the abdominal muscles.

The only abdominal support worthy of mention is an adhesive plaster dressing, applied as follows: The abdomen should be shaved, for obvious reasons. The patient should stand perfectly erect. Then begin with two-inch zinc oxide adhesive, starting the dressing one inch beyond the median line, low toward the pubes, letting it come upward and onward, just above the crest of the ilium, and stopping one inch short of the median line in the back on the right side, then a similar one on the left, and this should be repeated on either side, overlapping in front but not in the back, until the various strips of adhesive are carried up to, but not including, the umbilicus. This method, of course, has one very objectionable feature, that of skin irrita-

tion when worn too long. This form of dressing may give considerable relief to patients who will not submit to operation, or who, from some physical cause, are not good surgical risks. Likewise, it is a good dressing to give support during the five or six weeks of convalescence following nephropexy. Those who advocate the wearing of certain kinds of corsets will find this dressing to be of great service, and one which will not interfere with the wearing of the corset.

There are a few points in connection with the operative treatment that are worthy of mention. One method, which is still advocated by some writers, consisting of packing the wound in the back with gauze after suturing the capsule to the muscle, allowing union by granulation with a view of obtaining stronger adhesions between the kidney and abdominal wall, need only be mentioned to be condemned.

The reckless handling of the kidney in freeing it of the fatty capsule, and by bringing it out through the wound in back is wholly unnecessary, though it is still advocated by some good operators. This is not only unnecessary, but the kidney may be done much damage. It should be remembered that the fatty capsule is there for an anatomical purpose, and should not be sacrificed. All that is necessary is to divide the fatty capsule longitudinally, by blunt dissection, and reflect it to either side. This gives you a good view of the fibrous capsule, which should be divided a little to the outer side of the convex border, from pole to pole, and reflected on either side about one-half inch, then sutured on either side to the muscle, being exceedingly careful that all of the fatty capsule is well beyond the suture line and well out of the field of the lumbar wound.

I have found by experience that the best incision is one made at the outer border of the erector spinae muscle, extending from the twelfth rib nearly to the ilium. You will encounter the ileo-hypogastric nerve, which may sometimes be double. This nerve should not be cut, because it supplies the skin over the side of the abdomen and crest of the ilium with sensation, and, if injured, it will cause much pain, and if severed, the patient will complain of a peculiar numbness, sometimes for many months. The surgeon should be careful also, because such an accident will cause the patient intense suffering for two or three days.

Fullerton's technique of using a strip of the fibrous capsule for the purpose of fixing the kidney to the twelfth rib in the manner so elegantly recommended by Mr. Billington before our society recently, is most heartily condemned by the best surgeons in this country and in Europe. Sir Frederick Treves, of

Mr. Billington's own city, condemns the technique in no uncertain terms. Personally, I have never used this method for the following reasons: First, you have to handle the kidney roughly by bringing it out through the wound in the back in order to strip down the capsule from the upper pole. Second, such a strip would not be strong enough to hold, and would tear off the first time the patient coughed or vomited. Third, the kidney has normally, a free vertical excursion within its fatty capsule, of at least one to one and one-half inches, on respiration, and the main object of nephropexy is, not to fix the kidney, but to anchor it, and if this strip of the fibrous capsule should hold, it would be fixed and not anchored. Fourth, normally the kidney and ribs have diametrically opposite movements on respiration, and this alone, it seems to me, would be a contraindication to such a procedure.

In dressing the wound it is best to use only a small piece of gauze, held in place and protected by adhesive plaster passing well around over the abdomen to insure support to the abdominal viscera.

One of the most important points in the post-operative treatment is to avoid the use of opiates as far as possible, as they produce nausea and vomiting, conditions certainly to be avoided.

Another important procedure is the elevation of the foot of the bed about eight or ten inches, in order to secure the benefit of gravitation. The patient does not notice nor complain of this position, which should be maintained for about fifteen days.

The bowels should be kept regular by enemata in order to avoid constipation. Enemata are much better and safer than purgatives, which often cause nausea and vomiting.

The patient should be kept in a recumbent position for twenty-one days following the operation, and should be cautioned against violent exercise or jarring during the period of convalescence.

DISCUSSION.

Jno. R. Wathen: In view of the very exhaustive paper Dr. Peak has presented on this subject, and in addition to the papers read before this society by two noted Englishmen on a recent occasion, it is difficult, in a discussion of this subject, to present anything that will be at all new.

I think we are unfortunate in having the term "movable" kidney or "floating kidney," for the reason that it may sometimes lead us to overlook the fact that, from an anatomical point of view, the kidney should move. We all know that the normal healthy kidney should have an excursion, upon inspiration, of at least one inch. In very pronounced general enteroptosis, where all

of the abdominal viscera are partially dislocated or freely movable, possibly due to a colon full of fecal material pulling upon the ligaments, we may have a kidney so freely movable that I doubt whether, in many instances, surgical treatment will be of any benefit. Hahn was the first to call attention to movable kidney and to discuss the symptoms accompanying this condition. We are all familiar with Diell's crisis, and other diagnostic points pathognomonic of this condition. However, it remained for Edehols, twenty years ago, to recommend and practice surgical treatment of this condition with any degree of success. He has further called attention to the fact that chronic nephritis is frequently associated with movable kidney, and that when the kidney is partially decapsulated, the chronic nephritis is benefited, which is a very valuable point.

As to the frequency of the occurrence of movable kidney, it has been estimated, by a German surgeon, that it is found in one of every twenty-two women, and in men, in one of every two hundred and seven. Whether or not pregnancy has anything to do with it is a question. It has been estimated, by some Austrian surgeon, to occur in as many as 40 per cent. of women who have not borne children.

Now, as to diagnosis of this condition by palpation. On the right side the kidney can be palpated in possibly 60 per cent. of cases; on the left side, in 8 per cent. of cases in men and 30 per cent. in women. There is undoubtedly a congenital condition associated with movable kidney, just as in enteroptosis, we find it in many members of the same families. I will not go into the causes that produce this condition, because they are as yet little understood.

I believe that intraabdominal pressure will tend to relieve this condition. That is really the ground upon which is based the use of corsets, and kidney supporters, but it has always appeared to me to be quite a different proposition from the use of a truss in hernia, because, in the latter condition, we can, to a certain extent, obliterate the canal by pressure and hold it in place, but to fit a corset so that it will hold a kidney, which is about the slipperiest organ we have to deal with, is almost impossible.

As to treatment, it has been estimated that surgical treatment will cure from 65 to 78 per cent. of cases, but at least 20 per cent. of all operations will be, to a certain extent, absolute failures. In my opinion, the best treatment for movable kidney is, and will always be, some surgical procedure, and we must select the operative procedure that is best suited to each individual case. The object of the operation, as demonstrated by the Englishman mentioned as well as others, is to sustain the kidney and hold it in place by means of the capsule and otherwise; therefore, we should entirely close up the dead space left when the kidney is replaced from the place into which it originally sank behind the colon, and thus se-

cure additional support for the kidney at that point. A long incision should be made in order to enable us to close up this space below the kidney. In my opinion, the incision recently recommended by Dr. Mayo is the one that should be adopted.

I think any operative procedure for fixing the kidney in position is better than depending upon outside pressure from corsets and other supports, because here we are working in the dark and are unable to prophesy anything in the way of a positive cure.

W. F. Boggess: Dr. Peak did me the honor to ask me to open the discussion of this subject from the internist's point of view, and I very much appreciated the fact that he considered that there is any medical side to this proposition, especially as he has told us in the paper that nephropotosis is always a surgical condition. However, I am of the opinion that there is a medical side to many of these surgical subjects, and this holds true in nephropotosis, even more than in appendicitis. The medical side consists, primarily, in diagnosis, and if there is any one thing that is of more importance to the patient than another, either in appendicitis or nephropotosis, it is diagnosis. In nephropotosis, however, I go further, and say that, not only is the question of diagnosis one for the internist, but that there is a medical side to the treatment of any of the visceroposes and especially nephropotosis. The subject of movable kidney is one of the most difficult problems with which the internist has to deal. Any amount of splanchnopotosis, or other visceropotosis, is entirely compatible with good health and perfect nutrition. Not every one with floating or movable kidney is diseased; not every one should be operated upon. Many persons will carry a movable kidney, or a general visceropotosis, for a long time and remain in perfect health. It seems to me that surgery in nephropotosis should be restricted to those cases in which there are symptoms local in character and entirely dependent upon the misplacement of the kidney, such as Dietl's crisis, attacks simulating renal colic, localized distress, etc. In such cases I agree that the kidney should be anchored by a capable surgeon. But, unless we have local symptoms distinctly referable to the kidney misplacement, I do not think it is a suitable case for surgical intervention, and especially if the kidney misplacement is a part of a splanchnopotosis and a general visceropotosis, in which event I do not believe that simply anchoring the kidney will give the patient any relief other than that produced by the rest enforced and the psychical effect of the operation. Again, if there are certain constitutional conditions such as indigestion, constipation, neurasthenia, hyperchlohydria, either sensory or motor disturbances, that have resulted from the visceropotosis, anchoring the kidney does not give the relief expected, because these chronic conditions, although primarily due

to the kidney misplacement, will continue after the operation.

I must confess that my experience in cases that have been operated upon has not been encouraging. Whether it has been due to faulty technique on the part of the surgeon, or whether nephropexy does not do what the surgeons claim for it and leads to exstrophy, I am unable to say.

There is a medical side to the treatment of general visceropotosis, as well as localized nephropotosis. There have been other writers since Glénard's time, but I do not think they have improved upon his monograph describing the symptoms resulting from misplacement of the kidney, not do I believe we have made material advances in the medical handling of these cases. He outlined the following methods of treatment: First, replacement of the abdominal viscera, whether the stomach, kidney, colon, or what-not, by mechanical means, if possible. Certain misplacements of the kidney may be relieved, and the patient made comfortable, by means of mechanical appliances. Second, improvement of the nutrition. This is absolutely necessary. The kidney is normally held in place by the peri-nephritic fat, which, in many of these cases, is practically entirely absorbed. Therefore, by improving the patient's nutrition, we increase the peri-nephritic fat and also strengthen the abdominal muscles, and the kidney is thus held in place by natural means.

Constipation is another very important point. As Dr. Wathen has truthfully said, the constant sagging and pulling of the colon or large gut, filled with fecal material, has a tendency to pull the kidney down with it. In such cases we must back up the constipation if we expect to accomplish anything in the way of relieving the misplaced kidney.

Next, the treatment of the neurasthenic stage. This comprises the medical treatment of nephropotosis, and until it has been thoroughly tried without results, and the patient has local symptoms referable to the misplaced kidney, I do not think we are justified in sending the case to a surgeon for replacement of the kidney by surgical means. I believe that the number of cases of nephropotosis that require nephropexy is very small in comparison to the total number of such cases that we see. Furthermore, I believe that when such operative procedure is carried out, by a competent surgeon, we should expect good results from it just as we expect good results from herniotomy, and other operations of like character.

Curran Pope: I would like to say just a few words, consisting largely of a reiteration of my remarks in the discussion of papers read by Dr. Suckling and Mr. Billington on the occasion of their recent visit to this city. From the standpoint of the neurologist, we do not recognize such a condition as the "neurasthenia of nephropotosis." However, we may have **neurasthenoid**

symptoms, or symptoms that resemble neurasthenia, in cases where there is a kink in the ureter. We oftentimes have neurasthenoid and hysteroid symptoms which are the result of the toxemia which occurs from mechanical obstruction, but we have not, in the true sense of the word, a neurasthenia.

I would like to supplement Dr. Boggess' remarks as to therapy, and also to mention several other conditions which should lead us to not send these patients to the surgeon for operative procedure. One of them is surgical contraindication. Some of these patients are not in condition, in any sense of the word, to stand a surgical operation, and we certainly could not justify ourselves in sending such a patient to the surgeon for operative work.

It has always seemed to me (and we neurologists see a good many of these kidneys misplaced in varying degrees) that the physician's mind has ceased to cerebration at the point where he applies mechanical pressure to the abdominal wall in these cases. He seems to forget that the abdominal wall is composed of muscular tissue in a number of layers; that this muscular tissue is capable of contraction and, therefore, capable of development, and that we have a painless, easy and simple method of strengthening, not only the abdominal walls, but the individual layers, if we choose, on either side of the abdominal wall, by means of the sinusoidal current, which will produce strong, powerful, painless contraction, relieves constipation and strengthens the abdominal walls. Personally, I believe that if I had a patient, whose symptoms I believed to be solely due to a misplaced kidney, and whose general condition was otherwise good, I would unhesitatingly suggest to that patient that the quickest and best and safest thing to do would be to have the kidney replaced by surgical procedure, thus correcting the deformity, so to speak. But there are many cases in which we should not even contemplate a surgical operation. While we may classify nephroptosis as a strictly surgical condition, still we must remember that oftentimes these "strictly surgical conditions" find the patient in such condition that operative procedure cannot be undertaken with safety, and we are compelled to give them medical instead of surgical treatment. It seems to me that we should practice conservatism in both surgery and medicine, and avoid making sweeping assertions that such and such a condition is a strictly medical or a strictly surgical one. Furthermore, I do not believe that, under present-day conditions, medicine can possibly get entirely away from surgery, nor surgery entirely away from medicine, and that, after all, it resolves itself into that old, time-honored profession, that when you sit down to study a case, the best thing to do is to bring into play just a little bit of good hard common-sense and brains.

Wm. H. Wathen: I have been operating for

movable kidney for nearly twenty years, beginning soon after Edebohl began his work. I had the pleasure of witnessing some of his early work and admiring his beautiful technique. I have read no description of any operation, before or since, that I think is superior to that of Edebohl. The trouble is that a good many operators only imitate Edebohl and they do not get good results. His operation is simple and practically devoid of danger. It gives a good area of the de-capsulated kidney that is brought into contact with the thoroughly denuded surface of the posterior wall of the abdomen, to which it becomes adherent. I do not agree with Dr. Peak that, after the fixation of a kidney, it should still have a certain degree of mobility. There could be but little mobility following an operation after the method of Edebohl, in view of the wide area of adhesions which results, nor do I believe there is any necessity for mobility. In a number of women who had been operated upon after the method of Edebohl, and permanently cured, I was not able, upon examination, (through very thin walls in most instances) to detect any mobility of the kidney. Only a few days ago it was reported to me that a woman, upon whom I had operated last fall after this method, had been relieved of all of her symptoms. Less than a week ago I operated upon another woman after the same method, and I anticipate a permanent cure of the condition on that side; later I may operate for the fixation of the other kidney.

The question sometimes arises, what shall we do in cases where we have bilateral nephroptosis. Generally speaking, we may operate, with perfect success, upon both kidneys at the same time. I did not do so in the case I mentioned for the reason that the total solids eliminated in the urine was far below the normal, and the percentage of urea was also not up to the normal. Therefore, I did not desire to take any risk of crippling the functioning powers of the kidneys. Had the excretion of solids been equal to or above the normal, and the percentage of urea likewise, I should have operated upon both kidneys at the same time.

As to the incision, I prefer a straight incision down just to the outer border of the erector spinae in cases where there is a reasonable length of ileo-costal space, and through this the kidney can be readily delivered. As to working upon the kidney and fixing it without removing it through the wound, I take no stock in this whatever. A kidney to be operated upon properly and fixed correctly, must be removed through the wound, the sutures properly introduced, and the kidney to fall back.

In doing this operation, we must be careful to separate all of the fatty capsule from the abdominal wall, going back far behind the kidney so as to avoid the possibility of injuring the colon or making an opening into the peritoneal cavity. Then separate the capsule from the kidney, push-

ing most of it in front. When the kidney has been fixed, close the wound.

Every case of simple misplaced kidney is not an operable one. A movable kidney superimposed upon an inherited neurasthenia is not an operable case, as a rule. A case of acquired neurasthenia, or, as Dr. Pope calls it, a neurasthenoid condition as the result of a movable kidney is always, with few exceptions, an operable one.

No one has said anything about digestive disturbances in movable kidney. In a large experience with these cases during the past twenty years, I have found that the conditions which give the most trouble are two in number; namely, digestive disturbances and nervous disturbances. The disturbance of digestion is caused chiefly by the pulling down of the pylorus and duodenum by the sagging of the kidney, and this is usually relieved, in operable cases, by proper fixation of the kidney.

In regard to constipation resulting in movable kidney, I believe this is true to a certain extent, but not to the degree that may be imagined from the remarks that have been made here to-night. We will find nine cases of movable kidney on the right side to one on the left. We know that on the left side the bowel does not exert any great amount of pulling upon the kidney, for the reason that on the right side we find a comparative liquid condition of the feces, while the opposite is true of the left side. Furthermore, on the right side there is no fixed condition of the hepatic flexure, whereas on the left side we have a fixed condition high up, about the ileo-costal ligament. Therefore, we do not have as much pulling down of the kidney by the bowel on the left side as on the right.

Guy P. Grigsby: I have had opportunities for seeing a great many of these cases of misplaced kidney. It is a peculiar fact that when a surgeon discusses a subject of this kind, he looks upon it entirely from a surgical standpoint and advocates radical methods, while the medical man looks at it entirely from his side. It would seem that we might strike a middle-ground and have a sane and rational discussion of these subjects.

I have seen a good many nephropexies performed and the result has generally been satisfactory. Undoubtedly, however, many of these cases are operated upon that do not need operation. I have seen several cases operated upon in which the symptoms supposed to be due to a floating kidney did not clear up after the operation. I think Dr. Bogzess has very concisely stated the situation. Most of these patients are in a very emaciated condition, in whom the fat or adipose tissue that normally supports the kidney is lacking. Frequently such cases can be cured without operative procedure, and if we must err, it is better to err upon the side of conservatism.

Louis Frank: I was glad to hear Dr. Grigsby say what he did. I am not in accord with

everything that the surgeons have said here to-night. My own experience has been that, if all patients, of either sex, who come under my observation with movable kidney, required surgical intervention, I would be kept so busy anchoring kidneys that I would not have time for anything else. I had thought, from the great amount of discussion of this subject some years ago, at the time that Edebohl brought out his book and first published his articles and from the conclusions arrived at by men of vast experience since that time, that this subject had been pretty well settled. That some men have met with a lack of success, I think has not been so much due to any fault of the particular operation carried out for the cure of this condition, as it has to the fact that the cases were illy selected. However, there is no operation, that has been done by operators other than the essayist to-night, that has not occasionally resulted in failure; his experience differs from that of all other men who have done work along this line.

The question of movable kidney should be considered from two different standpoints; namely, those that occur in the normal type of man or woman, and those which develop in the tenth or twelfth year of life. The latter type occurs in those children who have other stigmata, such as a narrow chest, narrow epigastric angle, etc., which continue through life, and this is an entirely different condition to that which we see in women with lacerated perineums, who have borne a number of children, with lax anterior abdominal walls, etc. I have learned in late years from observation of the work of others as well as from my own experience, not to operate upon these cases merely because the kidney is movable. In not one out of fifteen or twenty of these cases that come to me do I mention the fact to the patient. In some instances I advise them to go to a neurologist for treatment to improve their general condition. There is a certain type of cases, however, that do require operation, but they cannot be picked out by a mere physical examination in the office; it requires very careful and painstaking examinations and observation to recognize them. These are the cases that have Diehl's crisis, due to obstruction of the ureters. If we will examine them with a ureteral catheter, we will usually find considerable dilatation of the pelvis of the kidney, exfoliation of the pelvic epithelium, or a bacteremia. These are the cases that should be operated upon for fixation of the kidney.

Another type of cases is that in which there is more or less gastropexia, or enteropexia, in addition to movable kidney. This can be easily detected by giving the patient a bismuth meal and having a radiograph made. They can be isolated from the other type if we will give these cases the careful study that they deserve. I do not believe, however, that just because the patient has a movable kidney, which makes an ex-

cursion down into the pelvis or to the other side of the abdomen, or where we can get the hand between it and the ribs, we are justified in advising an operation. That is not the right sort of surgery, and is not the kind that will serve to maintain surgery in good repute.

I was surprised to hear Dr. Wathen give as a reason for not operating upon both kidneys at the same time, that the excretion of solids and percentage of area were below the normal. Such being the case, it would indicate existing insufficiency of both kidneys, and he should not have operated upon the patient at all at that time.

I was also surprised at the essayist's statement that, after operation, the kidney should have an excursion of at least an inch. I cannot conceive of any operation upon the kidney that will fix it and still permit its normal range of mobility.

Hugh N. Leavell: This is an exceedingly interesting subject, from a medical as well as a surgical standpoint. I agree with one of the speakers that conservatism should rule. Whenever we find a woman who is conscious that she has something moving within her, whether a kidney, a colon, stomach, a live foetus, or what-not, we are in for trouble. Whether these conditions give rise to what Dr. Pope has termed *neurasthenoid* symptoms, I cannot say, but I am certain that, sooner or later, they usually become *neurasthenic*. If we will stop to consider how this trouble may get started, I think we will all realize that the paper this evening and the ensuing discussion has just "taken a little bit off the top," as it were. Dr. Wathen, in his discussion, said that the most immovable part of the colon was the splenic flexure. We will grant that for a moment. He also said that constipation is almost always the rule in these cases. We will also grant that. Now, if we have a colon, loaded with feces at the splenic flexure, does it not necessarily follow that it will, sooner or later, become angulated, and that this angulation will produce greater tension below the angle, which will finally cause the colon to be divested of its proper musculature, then become more than normally dilated, and still further tend to pull the kidney from its anchorage? It began then, if you please, with an enteroptosis, followed by auto-intoxication, resulting in interference with the musculature all over the body. It is not limited to the kidney, but also involves the musculature of the stomach, uterus, etc., and explains why we get such miserable results from fixation of the uterus in these "*neurasthenoid*" cases. It also explains why we do not get results by simply taking a "little bit off the top," and merely fixing the kidney.

I agree with Dr. Frank that we should wait for manifestations other than simply something moving inside the abdomen before subjecting these patients to operation. We should wait for disease symptoms, Dietl's crisis, and be sure that the function of the kidney is being interfered

with before we operate. As I said before, if we are looking for trouble, start to work on one of these cases. I have treated a great many of them, both medically and surgically, and they have not added to my reputation. I am quite sure that, with the style of nephropexy advocated, going in above and looking down upon the situation, as it were, we will not be able to accomplish the results described in the paper with which we have been so beautifully entertained to-night.

J. Hunter Peak (Closing): I am certainly glad that my paper to-night has been considered worthy of discussion at least. I do not hesitate at any time to say what I think in regard to these conditions. If you desire to take issue with me, all right; I will take it good-naturedly.

As the hour is growing late, I will not attempt to go into any of the points brought up by those who discussed the paper.

WEAK FEET.

By W. BARNETT OWEN, Louisville.

Weak feet, commonly known as flat feet, which is a most unfortunate misnomer, as all flat feet are weak but all weak feet are not flat. This is a condition of partial or complete weakening or stretching of the ligaments primarily, and of the muscles secondarily, having to do with the holding together and supporting the bones of the tarsus forming the instep, on which the body weight is supported. The result of this condition is to cause a partial or complete dropping of the instep, or arches, of the foot, with an everted attitude, causing the weight to fall upon the inside of the foot.

This condition is by no means a new one, nor will I attempt to give you anything new or original. Will endeavor to make this paper a strictly practical one, laying extra stress upon the points of most importance.

While there has been much said of this condition, there has been but little done, or but little properly done, as weak-foot is decidedly on the increase. It is stated by some investigators that three out of every five persons are so affected. There are many practitioners who fail to even think of this condition when examining their patients. On the other hand there are many who make the proper diagnosis, who sadly fail in their treatment. I regret to say that many doctors instruct such patients to go to the corner shoe-store, where they purchase a pair of so-called arch supporters to be worn even before the foot is ready for the proper brace which is moulded and made for that special case. The usual error in diagnosis is that of rheumatism. Many cases of weak-feet, pure and simple, are treated for months and months with the salicylates and other rheumatic measures. Of

course, they grow worse, physically and constitutionally.

Weak-feet can be divided into several classes: The simple weak foot, the flat and rigid weak foot, the traumatic flat foot usually following fracture or a sprain, and the paralytic flat foot, usually following anterior poliomyelitis.

Weak-feet may be complicated by repeated arthritic attacks and the so-called painful heels, which is a bony granulation with a surrounding periostitis at the tubercle of the os calcis.

PATHOLOGY.

According to Whitman, who has made a most extensive study of this subject, the pathology is briefly as follows: Supposing the foot to have been normal before it began to break down, it is evident that persistent deformity could not have been acquired without marked changes in its internal structures. The ligaments on the internal aspect of the foot and of the ankle joint are weak and distended. The unused portions of the articular surfaces of the joints may be denuded of cartilage, while new facets may have been formed to accommodate the changed relations of the bones. For example, the external malleolus may be in direct contact with the os calcis. Evidences of injury and of abnormal pressure may be found in the thickened periosteum, while the internal structures of the bone has been changed in adaptation to the new conditions. The muscles which are no longer used in the leverage function, the plantar flexors and the abductors, have become atrophied, a change that is made evident by the shrunken calf. The muscles on the inner border of the foot have been overstretched, while those of the upper and outer part have become shortened and contracted. By far in the greater portion of cases the pathological changes have not advanced to a stage that interferes with successful treatment.

SYMPTOMS.

For convenience these may be divided into subjective and objective, which vary under the different types of weak feet.

Subjective symptoms are, weakness and pain, which are increased when standing and walking, greatly relieved by rest. The pain begins in the heel and ankle, and is referred to the calf, thigh and back. Damp weather frequently increases the above symptoms.

Objective symptoms are, limitation of motion, especially adduction, with an ungainly, slouchy gait, muscular spasm, stiffness, swelling after long standing, distended veins, and usually the arch has partially or completely disappeared. The most reliable symptom of all in beginning weak foot, is pain

when in use, disappearing under rest or the proper support.

TREATMENT.

We want to shift the weight of the body from the inner border of the foot to the outer. The first step is to break up the adhesions about the foot and ankle joint by forcible stretching, followed by strapping the foot in an over-corrected varus position, after the method described by Gilbey, as was used by him first for sprained ankle, allowing the dressing to remain about five days. This procedure to be repeated until the normal range of motion can be obtained. Except in advanced rigid feet, and paralytic flat feet, this first step will correct the deformity. The extreme rigid foot will necessitate the same manual stretching under general anesthesia, and the application of plaster bandage, extending from the toes to just below the knee, the foot in extreme varus and at right angles. In some cases it is even necessary to cut the tendo-Achilles in addition. This dressing is to remain for three weeks, allowing the patient out of bed the third day, and encouraging him to walk with crutches. The weight of the body will further benefit the correction while in this position by stretching the muscles and ligaments on the outer side of the leg and allowing the inner muscles to contract and resume their normal tone. When this bandage is removed the foot is reduced to its normal attitude, and a plaster cast is taken for a Whitman brace to be made. The plaster bandage is then reapplied in the over-corrected position for another week. Then active massage and stretching is instituted daily, in hot salt water. (I believe the hot-air machine would be beneficial right here.) The patient is allowed to walk only with the brace in the proper shoes. We must remember that the brace does not correct deformity, but merely supports the foot in the correct attitude, and prevents recurrence of the deformity.

While making casts of feet is simple, it requires considerable work, and it is very important work that cannot be trusted to an inexperienced assistant or an instrument-maker. Unless it is done properly, it is absolutely useless. The method is condemned and abandoned as worthless, while we are alone to blame. At least 99 per cent. of the shoes as manufactured at present, fit the eye and not the feet. If it had not been intended that our toes should functionate separately, as well as collectively, they would not have been separated. How many people do you know who have no corns or bunions? The percentage must be extremely low. The improper shoe is to blame in every case. There are a few fairly good shoes made for normal feet.

For the treatment of weak feet, in addition

to the correction of the deformity and the application of the brace, the heel and sole of the shoe should be raised from 1-8 to 1-4 of an inch on the inside, which is an extra aid in shifting the weight to the outer border of the foot. Some beginning cases can be relieved by the adhesive strapping previously mentioned, and the application of the proper shoe, not being sufficiently severe to require the use of the brace.

The paralytic weak foot is treated by open operation, consisting of tendon transplantation and arthrodesis, with the above mentioned brace and shoe to maintain the normal attitude.

CONCLUSIONS.

1. The shoe should be made to fit the foot and not have the foot molded to the so-called stylish shoe.
2. The bad points of the ordinary fashionable shoe are, too narrow across the toe, an outward tendency instead of an inward twist, heel too high and narrow. The shoe should fit the ankle snugly.
3. Children should be trained to walk with the feet parallel instead of being encouraged to turn them out, which is the beginning of the deformity.
4. Early diagnosis and treatment prevents much pain and deformity.
5. Examine your patients' feet as a routine practice.

DISCUSSION.

J. B. Richardson, Jr.: I am very glad of an opportunity to emphasize some of the points brought out by Dr. Owen. As he stated, in dealing with this condition, our attention should be chiefly directed to the prevention of deformity in the beginning. The point made by the essayist in regard to teaching children to "toe in," rather than to assume a more graceful but more harmful attitude, is well taken. We have all seen parents who insisted upon their children walking with their toes turned outward, thereby putting them in position to become deformed about their feet. No person who habitually toes in develops this deformity. Certain races that wear sandals, or go barefooted, all toe in and all have excellent feet.

The point made by the essayist in regard to the toes functioning separately as well as collectively, is also well taken. I doubt whether five per cent of the men present here to-night are wearing shoes that would fit normal feet. The argument usually presented is that they are comfortable and do not hurt the feet. Their feet are deformed, and in most instances have been deformed from infancy up. A shoe to fit the normal foot, should be broad at the toe, allowing them to spread, and the heel should be low. The average shoe of the present-day does not allow any spreading of the toes whatever.

The idea of applying a brace to a rigid foot is so perfectly foolish, when we stop to consider the pathology of the condition, that no one who understands it would think of applying a brace to a foot that had not been rendered limber. In many instances this takes a long time. Patients in whom the os calcis has been dislocated for months expect to be relieved in a short time. This is impossible. Stretching must be practiced for months and months before it can be accomplished.

Some years ago I read a paper on this subject before the medical section of this society, and since then I have treated a number of cases through the kindness of various doctors who have sent them to me. I have found that in private practice these patients are harder to deal with than are clinical cases. The former expect much more rapid results than we are able to accomplish.

The paper is a very good one, and the point to be especially emphasized is that we should wear shoes of the proper shape and fit for the normal foot.

F. T. Fort: I have enjoyed the doctor's paper very much indeed. Flat-foot seems to be a disease of civilization. If we go back to the sculpture, especially that of Hermes, we find that the big toe is absolutely straight and the weight of the body passed through the second toe. Then when we come on down to the gladiators, we find that a strap which held the sandal turned the little toe in, and that caused a slewing of the foot. And so on, up to the present day, when the majority of cases of flat foot are due to ill-fitting shoes, and rickets during childhood. Now it is a hard matter to find a properly fitting shoe.

I believe it is a fact that there are more cases of flat-foot in Germany than in any other country, for the reason that the accoutrement of the German soldier weighs about ninety pounds, and this, added to the weight of the individual, on forced marches, causes an ischaemic condition to develop in the ligaments connecting the tarsal bones, which then give way. I have in my pocket a little brace which I make myself, after the method of Prof. Joachimthal, of Berlin, using acetone and celluloid. It is made to fit the foot and is worn inside the shoe. With this brace a great deal of the pain and discomfort of flat foot can be relieved. Of course, as Dr. Owen has said, to effect a cure the condition must be broken up, but I believe that if we would all think more of the use for which our feet are intended than of beautifying them, we would see a great deal less of this condition.

A. C. L. Perciful: I wish to touch upon just one point; namely, high heels. In my experience I have found that high heels have been one of the most frequent causes of weak feet. Many of these patients who come to us complaining of pain in their feet, have been wearing high heels so long that the tendo achilles has become shortened, and if we have them discontinue high heels

abruptly, lowering the foot from an inch to an inch and a half all at once, the tendo achilles does not give way, but the arch of the foot does, resulting in a great deal of pain. Therefore, when we believe that the condition is due to high heels, their height should be lessened by degrees so that the foot may gradually regain its normal shape.

A. R. Bizot: Dr. Owen stated that changes of the weather increase the pain in this condition. What is the reason for that if they are not of a rheumatoid, or similar nature?

C. H. Harris: I would like to ask Dr. Owen if he means to imply that we should teach our children to walk "pigeon-toed" rather than the way which comes natural to them?

Guy P. Grigsby: So much has been said on this subject that it only remains for me to most heartily indorse everything that Dr. Owen has said in his paper. This is, to my mind, a most important subject, because of the frequency with which we meet with cases of weak feet. Unfortunately, the profession in general does not seem to recognize this fact, and to this is probably due the ignorance, or lack of knowledge of this condition, that we often see displayed in the treatment of these cases. As has been brought out, the incorrect shape of the shoe is often the direct cause of flat foot, in connection with improperly or tightly fitting socks or stockings, causing a faulty attitude of the foot.

One point that I would like to emphasize is the occurrence of flat foot in childhood, often in very early childhood. These cases are frequently overlooked, or neglected, and the child goes through a period of pain and discomfort and ends up with a broken arch, causing a faulty gait—the typical, stiff, flat-footed walk. I am sure that every physician here has had parents bring their children to him complaining that they were so dreadfully "pigeon-toed." These cases should make us at once suspicious of the possibility of weak feet. Almost invariably this is an attempt on the part of Nature to make the child assume a more correct attitude in walking, and you will find that as soon as you relieve the strain on the arch of the foot, the "pigeon-toes" will correct themselves.

One mistake that is frequently made is the application of braces to rigid feet. This, to my mind, is a mechanical impossibility, simply because the foot is unable to conform to the shape of the brace, no matter how correctly the latter may be made. The foot should first be stretched until it is pliable and can be moved in all directions; then it will conform to shape of the brace when the latter is applied. The brace is not intended as a support; its object is to cause the patient to assume a more correct attitude or gait, in walking. For that reason the brace should be made of some rigid material, so that when the patient abducts the foot or assumes a faulty attitude it will cause him enough pain to make him turn his foot to the

outside. In other words, the brace simply makes him acquire the habit of walking correctly, and when you have accomplished this, you have usually effected a cure. For this reason, braces which are built simply with the idea of giving support to the arch will only serve to relieve the patient while the brace is in position; as soon as it is removed the pain and discomfort returns.

W. C. Dugan: I wish to indorse everything that Dr. Owen has said, and to emphasize the importance of correcting this condition thoroughly. If adhesions are present, they should be broken up, under an anesthetic if necessary. Then put the foot in a brace and keep the patient at rest until resolution has taken place. This is a condition which deserves more attention than is usually given it.

B. J. O'Connor: In my experience I have not encountered many rigid flat feet, unless there has existed some inflammatory condition. It looks hardly reasonable that a foot would become rigid unless a good many years had elapsed since the condition began. The average case of flat foot that we see has been of shorter duration, and is usually due to circumstances such as outlined by Dr. Foot, carrying heavy weights, etc. Furthermore, the muscles are very much weakened by prolonged illness of any kind. I myself suffered with flat feet following an attack of typhoid, and I noticed especially that, after any sudden strain, such as in stepping off cars, etc., my feet would be tender for a week or so.

The mechanical principles outlined by Dr. Grigsby should be borne in mind. Very few general practitioners possess the necessary mechanical skill to properly fit a brace. In the average case, however, I believe a great deal of good can be accomplished if the physician will instruct the patient to extend and flex the foot, giving it about twenty minutes exercise each night and morning. If this is kept up for some time, together with proper mechanics in walking, it will strengthen the tendons and ligaments and a good result will be obtained in the majority of cases.

C. W. Hibbitt: Flat feet formerly kept a good many men out of the army in this country, but they are now permitted to enlist, and particular attention is paid to the shoe that is issued by the Government. It is very broad at the toe, with a very low heel, and the men are instructed at the beginning of their service to walk on their toes, pressing their toes forward and pointing them down. This gradually teaches them to walk properly. One surgeon in particular has taken up this question of weak feet, and has suggested that the feet of each man enlisting in the army be measured, and a properly fitting shoe supplied, instead of making a large number of shoes of various sizes and issuing them more or less promiscuously as is now done.

John Karagiozian: We do not see flat feet in my country. There we do not have high heels, and every part of the foot is exercised and the

muscles developed. We have trouble in shaping the heads and you people have trouble in shaping the feet. In my country they think an egg-shaped head is wrong, and when the head is still tender the mid-wives begin to shape it, and when they have ceased the back of the head is generally flat. I do not think you can change the fashion, but you might tell your patients to use their feet sometimes without shoes. Of course, if they are short they like to have high heels to make them look a couple of inches higher. Outside of this I do not see any use for high heels; they are always injurious.

Louis Frank: I would like to ask Dr. Owen what is the percentage of flat feet in women as compared with men. The shoes worn by women of the present day are notoriously ill-fitting and badly shaped, and this is particularly true of fashionable women; still it is my impression that flat foot is not of frequent occurrence in the female sex; certainly, I have seen but few, if any, cases in women.

Edgar W. Stokes: I would like to ask Dr. Owen what success he has met with in teaching children to "toe in"?

W. Barnett Owen, (Closing): First I want to bring out one point that was overlooked in the paper; namely, diagnosis by inspection. I think the mistake is often made of simply looking at a foot and saying that the patient has a good arch, when, if we would test that foot out in different directions, adduction, flexion and extension, we would find limitation of motion and pain, especially upon adduction. Furthermore, upon going into the history, we will usually find that the patient has experienced pain while standing or walking, which was relieved by a period of rest.

As an illustration of how hard it is to induce patients to wear properly fitting shoes, I will mention one case in a young lady, who had the middle toe crowded in between the adjoining toes, or so-called hammer-toe, as the result of the high-heeled, narrow-toed shoes she had been wearing. First I tried to straighten this toe out and think I would have succeeded if I had had the cooperation of the patient in wearing a properly fitting shoe, but to do this she would have had to wear a shoe three or four sizes larger than the one she was wearing, and rather than do this she preferred to sacrifice the toe, which was amputated. The same condition prevailed on the other foot and was treated in the same manner. This case illustrates how difficult it is to induce some of these patients to wear shoes that are comfortable.

In regard to lowering the heels, I do not mention this to the patient because I do not think it is the first step to be taken in the treatment of this condition. The first thing to do, in my opinion, is to support the weak instep, turning the foot in and strapping it in the method described in the paper. Then when the heel is lowered, the patient does not experience the pain mentioned

by Dr. Percell from contraction of the heel cord.

In regard to instructing children to walk "pigeon-toes," as brought out by Dr. Harris, I think this is preferable to the so-called "slew-foot." However, it is not necessary for them to walk "pigeon-toed"; I do not think it would be a hard matter to train them to walk with the feet parallel. On the contrary, however, they are taught at dancing-school to turn the feet out, and they grow up with the idea that this is the proper way to walk.

The device shown by Dr. Font, which is really a plate rather than a brace, is quite an ingenious idea, although I do not believe it would result in any permanent benefit because, in the first place, it would not hold the foot in any particular position. The patient could abduct the foot with the brace on as easily as the could without it. The brace devised by Whisman is really a brace and not a plate. It takes hold of the joint in the weakest portion and holds it in the proper attitude.

As to the question of flat foot following typhoid fever, I do not believe these are typical cases of weak feet; it is general weakness, with contraction of the heel cord which results from lying in bed for such a long period of time.

As to the proportion of weak feet in regard to sex, statistics show that they are about evenly divided. While it is natural to assume that, because of the extremely faulty attitude resulting from the small and ill-shaped shoes which women of the present day wear, that we would find a much greater percentage of deformed and weak feet in women than in men, I do not believe that such is the case. From the statistics on the subject and from my own limited experience, I have found that as a rule, the class of women who wear this style of shoe are not required to assume a standing posture for prolonged periods; they are willing to sacrifice comfort for the sake of appearances for an hour or two, knowing that they can then go home and don more comfortable footgear. This is not true of many women of the working class, as an example of which I will mention the case of a young girl whom I saw some years ago. She was employed in a department store and was on her feet from eight o'clock in the morning until five-thirty in the afternoon. She had been treated for two years for rheumatism, had been constantly losing weight, was almost a nervous wreck. The calves of the legs had greatly atrophied, and the muscles of the feet were almost gone—a typical case of weak feet. The method of treatment described in the paper was carried out for nearly a year, and at the end of that time she had gained in weight, was relieved of all pain, and has remained well ever since.

In all cases of weak feet, properly treated, a favorable prognosis can be promised.

CLINICAL CASES.

FOREIGN BODY (BOTTLE) IN RECTUM; EXHIBITION OF SPECIMEN AND REPORT OF CASE.

By BERNARD ASMAN, Louisville.

In the latter part of October, 1911, Dr. D. D. Worden telephoned me that he had a case which presented some rather unusual features, and which he desired to refer to me. The history he had obtained was as follows:

Patient a male, age 35, laborer. Had been healthy all his life with the exception of some rectal trouble. On the day previous to the day he consulted the doctor, a fellow laborer had given him a bottle, containing some medicine, with instructions to pour it into his rectum for the purpose of curing his piles. He said that he had gotten down on his hands and knees and inserted the neck of the bottle, desiring to get the medicine as high up in the rectum as possible, he continued to push the bottle up through the sphincter. When the medicine began to escape it burned him to such an extent that he jumped, at which the entire bottle slipped into his rectum and beyond his grasp.

Dr. Worden stated that, with the forefinger inserted into the rectum, he was able to just touch the bottom of the bottle.

The man was sent to the infirmary where I saw him, and after an examination I ordered him prepared for both an anal and an abdominal operation, not knowing which would be necessary in order to get the bottle out of the rectum, but preferring, of course, to get it out by the anal route if possible. The patient was anesthetized. Upon stretching the sphincter muscle as far as possible without rupturing it, I at once saw that it would be impossible to reach up into the bowel, get hold of the bottle and withdraw it, and that to remove the bottle by the anal route would necessitate cutting the sphincter. Some authorities advise that in such cases the rectum be laid open in the posterior median line, down to the cecum; some even recommend the removal of the cecum in order to get more room; or the splitting of the muscle both anteriorly and posteriorly in order to make possible the introduction of the hand. I believed, however, and I am now more than ever convinced, that if the sphincter must be severed it should be cut squarely across and in the transverse anal line, not antero-posteriorly. In my opinion we can secure better union of the severed ends when it is cut in this way. Accordingly the sphincter was divided with one sweep of the knife, the incision being carried to the tuberosity of the ischium on the left side. This gave me sufficient room to in-

troduce my entire hand. The severed ends of the mucous membrane were held with small clamps, which served as retractors and prevented any great amount of hemorrhage, and the cavity itself was packed with gauze. The bottle was found firmly wedged in the bowel, above the uppermost valve of Houston, and the swelling and oedema of the tissues about it were so great that it could hardly be moved. Introducing my hand well up into the bowel I succeeded after some effort in getting a firm hold with my fingers and thumb, upon the end of the bottle and, by pulling as hard as I could, I was able finally to withdraw it. The bottle was full of soft fecal material and, following its withdrawal, there was a great gush of fecal matter from the bowel. This, of course, contaminated the wound, yet I felt that this was better than to have opened the abdomen. After thoroughly cleansing the wound by irrigation, it was carefully closed with several layers of sutures, and the severed ends of the sphincter were then brought into close apposition with sutures. The mucous membrane and the external skin were likewise brought together with sutures. A gauze wick was inserted for drainage, believing that, in view of the fact that the wound had been contaminated by this great gush of fecal matter, we could not reasonably expect union by first intention. The man was put to bed and had little or no elevation of temperature. In a few days he was allowed to get up and at the end of three weeks he went home, at which time he stated, in response to our inquiries, that he had just about as good bowel control as he ever had, but upon pressing him he admitted that his sphincteric action was not perfect. Of course perfect union of the muscle under such conditions could not have been expected. The weak place in the sphincter could be felt by gentle pressure, but he had good contraction of the other muscles and fair control. I think possibly a secondary operation will be necessary in order to get perfect results.

I have here a picture, made 14 or 15 days after the operation, which plainly shows the healed line of incision, although in retouching the picture the photographer has made the line appear much broader than it really was.

The bottle, which is also herewith presented, is seen to be quite large, and it is on this account that I am reporting the case. It is a "Welch's Grape Juice" bottle, and in its greatest circumference measures about 7 inches.

One question of interest is as to why this man inserted the bottle into his rectum. In citing the history of the case I gave simply the reason stated by the patient. It is well known that a certain class of sexual perverts

resort to the introduction of foreign bodies into the rectum for the excitation of passion. This case however, apparently, does not belong to that class.

DISCUSSION.

Granville S. Hanes: Many and varied reasons have been given for the introduction of foreign bodies into the rectum. One of the most frequent, I believe, is sexual perversion. Also, a good many foreign bodies are introduced because of pathological conditions in the rectum. I do not doubt that this man introduced the bottle for the reason he stated; at any rate, it is a very good story.

Objects are sometimes introduced into the rectum for the purpose of concealment. There is a very interesting report of a Frenchman, who was sentenced to prison, and having time to make some preparation, he took a little box, covered with the omentum of a sheep, and placed in it files, saws, etc., which he introduced into his rectum. While in prison he very naturally contracted peritonitis and died. This box was removed and these objects found in it.

I think that this bottle could not have extended very far up in the bowel, but it is astonishing how foreign bodies will sometimes ascend high up in the gut. Some have said that this is due to reverse peristalsis, but I believe that they simply follow the line of least resistance and, on account of the motions of the body, gradually travel upward into the bowel.

The literature simply teems with reports of these cases. One report concerns a monk, who once had the colic, and some friend introduced the neck of a bottle into his rectum, the bottom having been broken out for the purpose of introducing some medicine. The bottle passed up into the bowel; and, their method of removing it was a very good one I think. They simply had a little boy introduce his hand into the rectum, grasp the bottle and withdraw it.

The rectum has also been used as a part of the anatomy upon which to play practical jokes. Dr. Combs, of Indianapolis, in 1909, reported a case in which a man who had been drinking, went out into the forest near a railroad, laid down, and fell asleep. It is supposed some one passing by saw this man lying there drunk, introduced a beer glass into his rectum. In order to remove it the glass was broken and all the particles removed. To do this an incision was made through the posterior anal commissure. The wound healed and it was reported that the patient had complete control of his bowel.

Dr. Cook, of Nashville, reported a very interesting case, in which a little child, while playing with a dog, became conjugated, and quite a lot of trouble was caused. The anal muscles were lacerated and necessitated an operation, with good results.

In removing foreign bodies from the rectum

I believe there is one point that we all fail to thoroughly appreciate and that is the degree of distensibility of the anal muscles. They are very elastic and any object that has been introduced by any reasonable force can, in my opinion, be removed without incision of the muscles if sufficient time is employed to effect complete relaxation. When the object has passed up into the bowel and there is great oedema another complication is added which merits other considerations. If, however, the object can be easily reached with forceps, gauze can be pushed over the slick surface, which will make a secure hold for the forceps and then the foreign body removed.

Bernard Asman, (Closing): Of course, a case of this kind suggests a great many others that are found recorded in medical literature, some of which might be interesting to relate if time permitted. One in particular that is suggested to me, is reported in many of the books on diseases of the rectum, in which a man conceived the idea that if he blocked up the rectum after defecation, he would require less food to sustain life, and thus be able to get along without eating so often and so much.

As to the rectum being used as a butt for practical jokes, one is reminded of the famous Marchetti case, in which a pig's tail was introduced into a woman's rectum by a body of students, the bristles in the tail having been first cut short so that they would engage the mucous membrane. The tail was introduced with the bristles pointing downwards, and when an attempt was made to pull it out the result can readily be imagined. Its removal was accomplished in a very ingenious way. A string was tied to the end of the tail and a hollow reed was slipped over the string and over the pig-tail for its entire length, thus dislodging the bristles that were imbedded in the mucous membrane, after which its removal was an easy matter.

I am rather doubtful of the possibility of reverse peristalsis being responsible for the fact that these foreign bodies are sometimes carried high up in the bowel. It is more likely due to the movements of the body coupled with the fact that the bowel is not a smooth, straight tube.

When the object is of glass the greatest care must be taken that it be not broken in the bowel, because the sharp fragments would result in severe laceration of the mucous membrane if not the entire thickness of the bowel wall, thus causing severe hemorrhage which would be difficult to control. If high up the peritoneal cavity might be penetrated and the consequent infection would be serious if not fatal. A number of fatal cases of this kind have been reported.

While the anal sphincter may be stretched to a much greater degree perhaps than is generally supposed, the fact must not be overlooked that there is a certain well-defined limit to its distensibility and if forcible division is persist-

ed in after this point has been reached irreparable damage will be done, because of the tearing apart or rupture of its fibres, thus resulting in partial or complete loss of function. It is clear that the sphincter must be distended considerably more in the removal of a large object than required in its introduction for the reason that added room must be provided for the operator's fingers or instruments necessarily required to grasp the object, whereas in its introduction the force was applied from the outside.

Rather than risk rupturing the muscle it is much better, in my opinion, before lessening its tone by overstretching, to sever it completely at one point, because a severed sphincter can be easily repaired, if proper attention is given to the prevention of infection of the wound, and perfect function preserved.

HYDRAMNIOS; REPORT OF CASE.

By L. P. DURRETT, Louisville.

On April 7th, 1911, I was called to see Mrs. L., who was having labor pains about every ten minutes, continuing every five or ten minutes apart. Made examination but could not make out anything on digital examination. Patient complained that examination gave her severe pain. The pains continued for 24 hours. Liquor amni expelled with each pain. On the morning of the 8th the pains lessened, I left patient. On the next day, the 9th, she was up and doing her housework, and continued to be up and about until the 15th. About nine o'clock in the morning. Pains continued all day, every three to five minutes apart. With each pain there was a free discharge of liquor amni; kidneys acting freely. There was enough liquor amni discharged to cause patient to change her gown three times, also pads on bed. About half-past ten that night, the patient became very nervous, spasmodic condition of her legs, which jerked like those of a jumping-jack. All of a sudden, patient complained of seeing snakes on left side of bed, and tried to brush them away. Had a wild delirious expression which lasted for an hour and a half, and did not improve until she had taken two drams of sodium bromide and two grains of denatured opium, which were given an hour apart, one dram and one grain of each.

On the morning of the 16th patient went to sleep and rested easy until five o'clock, when the pains came on again, lasting until eleven o'clock. On digital examination during this period of labor, the walls of the vagina were very much swollen and there was some difficulty in introducing the finger, as there seemed to be rolls of mucous membrane in the way. The os during all this time, dilated about the size of a half dollar, and you could feel the fetal head, which could be easily pushed up

out of the way. The patient would say, "I can feel you move the child." I left patient about eleven o'clock, April 16th, having pains very slight in character. Gave a dose of sodium bromide and opium. Called to see patient about five o'clock the same day and found her resting easy.

I asked if the kidneys had acted, and she said no. While I was there she passed about a pint of urine. While up she had pain and there was more liquor amni discharged. Made examination and could not find fetal head. I left and directed that patient be given 1-4 grain of morphine every hour until she slept. Patient had a good night. Was called on the 23rd, about seven o'clock, and found her having pains every three to five minutes apart. Upon examination found os dilated to about the size of a half dollar. Head presentation, which was very easy to move. Liquor amni continued to be discharged with each pain, during the night and the next day. Left patient on April 24th at nine o'clock, with instructions to take 1-4 grain of morphine every hour. Three doses were taken and patient rested easy all night. On April 25th found patient resting easy; no discharge. Complained of some abdominal soreness. Upon examination could not make out position of child. Abdomen flat and abdominal muscles flabby. Patient said she felt as if she had been delivered of her child. On April 29th, about nine o'clock, found patient in pain. Liquor amni escaping with each pain. This lasted until may 1st, at two o'clock, when the child was born. Head presentation, average child in size, being the 16th child, at full term, as twins had been born to this mother three times. Violent hemorrhage ensued, which was controlled by kneading the uterus and giving ergot. Placenta slow in coming away. Patient was very weak from loss of blood, and continued ergot and digitalis for twenty-four hours.

Patient and child got along nicely after this long siege of suffering. Mother and child doing nicely and mother returned to her housework on May 14th, and got along very well until May 23rd, when she developed mastitis which was such a severe attack that she was confined to her bed. It yielded to ichthyol ointment and hot applications by May 30. On June 3rd patient developed an attack of vomiting and diarrhoea, which lasted about twelve hours, when it was controlled. On June 4th patient had a quiet day and seemed to be getting along nicely. The night of the 4th, about one o'clock, she asked to be helped to the vessel, which was done, and she slid from the vessel onto the floor and was soon a corpse.

SUPRA PUBIC PROSTATECTOMY; WITH PRESENTATION OF PA- TIENT AND SPECIMEN.

By GEO. H. DAY, Louisville.

In comparison, the statistics of the two operations of prostatectomy rather tend to impress that the perineal is the method of choice, and granting that Young's mortality is 4 per cent. while that of Frayed is 7, the question arises: why this difference of 5 per cent.?

In reading Young's Case Reports, you are promptly impressed with Young the man, for his attention to detail, his preparation of his patient, his beautiful surgery, condition of patient on leaving the table, and then *his after treatment*.

In Freyer's reports he rolls off the cases by the hundreds, describing his operation very minutely, going extensively into the pathology of the gland, but strange enough, rarely mentions preparation or after treatment.

Young is the mechanic, the artist,—the Belasco, as it were—of surgery, while Freyer might be called simply the operator. Freyer's after treatment consists of inserting a rubber tubing 7-8 of an inch in diameter into the suprapubic opening, covering the tube and abdomen with absorbent cotton, allowing the cotton to absorb the over-flow. All of you know how that patient looks in a few hours,—literally floating in urine, which, aside from making the patient very uncomfortable, also tends to keep a couple of nurses occupied changing dressings, bed linen, clothing, and still *no drainage*. Freyer has never published anything as to a complete plan of drainage. True, he has advised a goose-necked shaped glass tubing to fit into his drainage tube, but which on all occasions has proven to be a miserable failure, because it does not fulfill its purpose, the urine overflowing between tube and abdominal wall, none passing through the tube.

Such an able surgeon as Deaver dismisses drainage with a scant dozen lines, saying in conclusion that the dressings will have to be changed twice daily on account of the over-flow of the urine.

Therefore the question naturally arises: If we could perfect a system of drainage in the supra pubic method, would we reduce the mortality to 5, or even 4 per cent., granting that Young and Wishard, who do the perineal exclusively, do have perfect drainage.

At the last meeting of the Kentucky State Medical Association, Bremerman read a very able article on this subject of post-operative treatment, at which time he described in detail his apparatus for complete drainage of the bladder. I have had the pleasure and good fortune to use a similar apparatus for

the past three years, and I believe that it settles for all time the very unsatisfactory question of bladder drainage. This method of siphonage was first introduced fifteen years ago by Dawbarn, to whom, I believe, most of the credit belongs. A number of others have used it since that time; however, none have introduced, so far as I can find, a solution to the abdominal end of the tubing; in other words, a rubber tubing the same size as the balance of the Dawbarn system, placed in the bladder cavity, is not practical, because the fluid passing down the long arm of the Y causes a very strong vacuum, the tubing is twisted about by this vacuum, and the distal ending is drawn to the wall or floor of the bladder, occluding completely the lumen of the tube. Then it was suggested that a glass irrigating nozzle be introduced into the cavity on the end of the tubing. This procedure had the same fault as the Dawbarn plain tube, always being stopped up by the bladder tissues.

I then tried the following: I secured a piece of fairly heavy one-inch rubber tubing; that is, the lumen is about one inch in diameter; and five inches in length. Very near the vesical end I cut two eyes, large enough for large clots to pass through. To the outer portion I fastened a small rubber catheter, passing from end to end, through which we can pass the different irrigating solutions. At the external opening I have a perforated metal stopper, with a large center opening, through which the small irrigator tubing passes. This opening is small enough to hold the tubing snugly. We then have the large tube acting as a caisson, the bladder contents coming through the eyes of the stationary tubes and being withdrawn by the smaller tube without the lumen being interfered with at all by the vacuum. The amount of siphonage is regulated, of course, by a shut-off on the long arm of the Y, so that just enough fluid passes through, to keep the bladder thoroughly dry. If a continuous irrigation is wanted, an irrigator is fastened to the catheter in situ, the flow is regulated, and can be continued indefinitely.

The above apparatus was used on the following case: Mr. J. H.; age 82; seen first July 13, 1910; family history negative; gonorrhea at the age of 30; has double inguinal hernia; seven years ago had a stroke of paralysis, from which he has never fully recovered; general arterio sclerosis; general condition grave; complete retention of urine for sometime, relieved only by the catheter; bladder very septic; pain severe and constant; sleep hardly possible; urine per catheter showed great quantities of pus and albumen; also excreting power of kidneys greatly decreased; prostate per rectum, large, bilobed.

high up, could not reach the apex, freely movable; patient suffering from acute septic absorption, which, together with his general health and age, made his condition quite serious. Owing to this grave condition the usual preparation was impossible, so that the operation was undertaken despite the great risk.

On July 16, with chloroform anesthesia, we enucleated the prostate in eight minutes and delivered a gland weighing 3 1-2 ounces. Following the removal, we massaged the prostatic cavity for several minutes, finishing the operation with very little hemorrhage.

At this time the patient collapsed; immediately went into deep shock. We started salines intra-venously. He was revived with great difficulty, put to bed in very grave condition. Saline was kept up, with the addition of strychnia, atropia, and digitaline, together with the usual after treatment. He remained in complete shock for several days. We instituted drainage immediately; irrigating solutions regulated; and after some days he rallied nicely. He was up in a chair on the tenth day, walking about some on the fifteenth day; passed sound on the 17th day; some incontinence of urine; supra pubic opening almost closed; left the hospital one week later; 60 days later he reports supra pubic opening all healed; says he is not troubled by any urinary symptoms; gained 20 pounds in weight; walks four miles every day despite his age.

I take pleasure in submitting the patient and specimen for your discussion.

DISCUSSION.

W. B. Owen: Dr. Day's report is so complete and the result so good that very little can be added. I had the pleasure of seeing this case and assisting Dr. Day in the operation. The patient's condition was very grave, being unable to get out of the bed without assistance. We thought he would surely die, but the result, so far, has been most happy. The wound healed up completely and has never re-opened. He has perfect control of his urine being able to hold it all night, and he feels better now than he has for many years.

One thing that I believe helped this patient as much as anything else, was the fact that we gave him a glass of water to drink every hour, in addition to the saline irrigation. This free use of water is recommended by Dr. Eugene Fuller, of New York City. A diuretic is indicated and water is the best. The preparation in this case was not as thorough as could be desired, because we thought that the patient would not live long, as his condition was not being improved under the treatment.

The drainage tube described by Dr. Day certainly does drain. While he has claimed no credit for these modifications, I believe they are original.

F. T. Fort: When we take all these cases of prostatectomy into consideration, I think it is remarkable how much work can be done on these old men and they live through it. A short time ago we operated on an old man whom we thought would die on the table, but he rallied and we were able to complete a suprapubic cystotomy and prostatectomy.

The after treatment which the doctor carried out was all that could be desired, except that I do not understand why he gave strychnia for shock.

The old persons seem to stand operations on the bladder as well as the younger ones; I have never seen one of them die.

TUBERCULOUS TESTICLE; EXHIBITION OF SPECIMEN AND REPORT OF CASE.

By JOHN W. PRICE, JR., Louisville.

The present case is one which I consider of some interest to both physicians and surgeons.

The patient, B. H., is a man 20 years old whose occupation is that of a school teacher in a small town. The patient's father, two brothers and five sisters are living and well. His mother died of erysipelas. There is no history of tuberculosis or tumor, cardiac, renal or nervous diseases in the family. Patient says that he has always been well until the present illness.

The present illness began in July, 1911. While riding horse-back he was thrown against the horn of his saddle and received a contusion of the scrotum. Almost immediately he noticed a swelling of the left testicle, and a week later noticed a swelling within the scrotum, which has remained constantly except for one week when it decreased in size during rest in bed. During July, August and September, 1911, he suffered almost constantly pain in the left testicle and scrotum. The pain was increased while standing. During these three months he lost about 20 pounds in weight. He was away from his work only one week of this time and does not know if he had any temperature, rather thinks that he did not. Since September he has had very little pain in the testicle, although the swelling of the testicle and scrotum persisted. During the past five months he has regained his lost weight.

On physical examination, we found a well nourished young man with abundance of superficial fat. Examination of the chest and abdomen shows the contained organs to be normal. Examination of the scrotum shows on the left side a heavy elastic, fluctuating pyriform tumor, which is dull on percussion. The overlying skin is freely movable, and the scrotum hangs away from the thigh. An en-

larged, slightly tender testicle is also palpated. The following diagnosis was made: A hydrocele with either an inflammatory (tubercular) or malignant disease of the testicle.

An operation was decided upon and a two-inch incision was made over the left side of the scrotum below the external ring. The hydrocele was found and the testicle appeared hard, inflated now to twice its normal size, and is densely adherent to the scrotum tissue, the tunica vaginalis contained milium tubercles. The cord is ligated with number 2 chr. cat-gut and the testicle removed. A strip of gauze is inserted in the scrotum and the incision closed up to the upper angle.

Tuberculosis usually attacks the epididymis primarily with the formation of one or more nodules which soften and discharge pus. It develops painlessly, and is usually bilateral. In infants, tuberculosis affects by preference, the body of the testis; it may have a subacute onset, appearing first as a hydrocele or a tender swollen testis. In making a diagnosis of tuberculosis of the testicle, we must consider syphilis and malignant tumors.

Gonorrhea of the testicle is sometimes symmetrical, usually bosselated or rigid, painless, densely hard, often bilateral, associated with moderate hydrocele, persisting for months; its growth is at first rapid and then slow. The cord is not involved. The history and associated symptoms of syphilis, the absence of inflammatory phenomena and therapeutic test confirm the diagnosis.

Malignant tumors of the testicle are usually either soft carcinoma or mixed sarcoma, which begin with trauma. There is usually a symmetrical and comparatively painless enlargement of the testis occurring in a few weeks or months after traumatism. The diagnosis must be made by incision and microscopic examination.

Through the courtesy of Dr. Leon K. Baldauf, we are able to show you microscopic sections of the testicle which we removed, and gross specimens of tuberculosis of the testicle, gonorrhea of the testicle, and round cell sarcoma of the testicle.

PATHOLOGIC REPORT ON SPECIMENS, BY L. K.

BALDAUF.

Specimen consists of a testicle opened, a portion of the cord and the tunica vaginalis. Over the entire tunica vaginalis were numbers of small milium nodules about 1 mm. in diameter. They were rather translucent in appearance. The portion of cord removed was distinctly infiltrated but showed no nodules. The testicle showed in lower pole a large caseous area distinctly yellow, and measuring 1 1/2 cm. in diameter. Surrounding this caseous mass there was an area of hyperaemia and marked infiltration of surrounding tissue.

Microscopically a number of new-formed blood vessels were visible and a mass of firm granulation tissue could be seen surrounding the area of caseation.

Macroscopic Diagnosis: Solitary tubule of testicle, tuberculous granulation tissue, milium tubercles tunica vaginalis, hydrocele.

Microscopic Examination: Portion of testicle outside caseous area examined microscopically.

The entire section is infiltrated with a number of splenoidal, polyhedral, plasma and round cells. This collection of cells is most marked in region of blood vessels and around some of remains of tubules. There is a distinct collection of new-formed blood vessels fibroblasts and rather old, connecting tissue. The old blood vessels show a marked endarteritis; the tubules are almost obliterated. The section shows the peculiar granulation tissue which is so often seen in this infection of the tissue.

Microscopic Diagnosis: Granulation tissue of tubercular origin.

DISCUSSION.

W. C. Dugan: At one time tuberculosis was regarded as a general rather than a local condition, but the profession has now come to recognize the fact that we may have surgical, or localized tuberculosis. The doctor has very graphically described tuberculosis of the testes, which usually begins as a painless nodule and is most frequently detected by accident. Later it becomes attached to the skin, softens, and begins to discharge, not pus, but a purulent material, or a tuberculous, cheesy material. The condition is usually chronic, but I have seen a number of cases that were very acute. I remember one that was as acute as any gonorrheal epididymitis I have ever seen. The patient was seized with a hard chill, the testicle swelled very rapidly, and within twelve hours after the initial chill it was several times its normal size. When the testicle was removed it was found to be studded with milium tubercles, the tunica vaginalis being also involved.

The idea has prevailed that we should take out the entire epididymis in these cases. Some of you will remember the specimens which I exhibited to this society a year or two ago. If one of those cases I did not take out the epididymis down to the bladder, notwithstanding the fact that the entire epididymis seemed to be involved. It was treated by the open method. The patient had emaciated until he was a mere shadow. He had a double testicular tuberculosis as a result of trauma. I did a double castration, and he made a complete recovery. He weighs more now than he ever did, and is apparently entirely free of any tubercular trouble.

The other two cases, reported at the same

time, I am glad to say, also made good recoveries.

I wish to indorse what Dr. Price has said in regard to complete castration in these cases. I do not believe that simple removal of the cheesy mass, as recommended by some men, meets the indications, and the same is true of vasectomy. The entire testicle should be removed, because it is absolutely of no service.

I would like to ask Dr. Price whether he has ever seen a case of acute miliary tuberculosis of the testicle?

Jo. W. Price: No, sir; I have not.

IV.

The Value of the Leucocyte Count in Acute Surgical Diseases; H. W. Hewitt, Detroit, Mich., Ann. Surg., XI, 1911-LIV, No. 6.

In acute surgical conditions the leucocyte count is of great value when considered in conjunction with the differential count. Formerly only total counts were made, but when made they alone were not of any great value. Of course it is understood that the clinical signs and symptoms must be considered conjointly with the laboratory findings.

Hewitt believes that, (1) The total count is an index of the patient's resistance to the infecting organism.

(2) The relative polymorphonuclear count is an index of the degree of, or severity of, the infection.

(3). If we have a relative polymorphonuclear count ranging between 75 per cent. and 80 per cent., infection is probable; if between 80 per cent. and 85 per cent., infection is usually found; if above 85 per cent., infection is almost invariably encountered, and this is regardless of the total number of leucocytes. In fact, some laboratory workers do not make use of the total count at all, but depend for diagnosis entirely upon the differential count.

Hewitt studied 100 cases of acute infections. He believes that when the polymorphonuclear neutrophile percentage is between 65 and 80 percent, the presence of infection through the count *per se* cannot be stated with any degree of accuracy. In acute inflammatory disease, in the pelvis, the polymorphonuclear counts are low; in the appendiceal region, the counts are higher; in the upper abdomen, both the total and polymorphonuclear counts are highest.

As is well known, the duration of the infection must be taken into consideration, since

infections, when of long duration, frequently overcome the patient's resistance and so vitiate the value of the count.

In differential diagnosis the negative value of the count is quite often of importance.

V.

Wright's Stain for Blood.

While Wright's stain has been in use for years, I desire to call the attention of the general practitioner to the ease with which this stain can be used in blood examinations. For differential blood counts, the busy physician needs a stain which requires no previous preparation of the blood film and which will stain rapidly and evenly. Wright's stain apparently meets these requirements perfectly.

Wright's stain (more properly "Wright's modification of Leishman's method") depends for its staining qualities upon eosinate of methylene-blue and eosinate of methylene-azure. It is possible to make this stain in the laboratory from methylene blue and eosin, but it is better to buy either the dry stain or the stain in solution. Precipitation will occur unless the bottle of stain is kept well stoppered. This precipitation is the result of the evaporation of the methyl alcohol with which the dry stain is mixed.

In using Wright's stain, the blood films should not be older than a few hours. The best results are apparently obtained when the films are stained before the lapse of two hours. Specimens weeks old do not stain well, and specimens months old stain very poorly.

The following method of using this stain has given excellent results with fresh specimens:

1. Cover the dried film of blood, which has not been previously treated in any manner, with a *noted* quantity of stain. Allow the undiluted stain to act for one minute.

2. Add to the stain on the film the *same quantity of distilled water* and allow to remain for three or four minutes. If the stain is allowed to act longer than four minutes a precipitate may result. The quantity of fluid on the specimen should not be so great that some of it runs off.

3. Wash in *distilled water* for 5 to 20 seconds or until the thinner portions assume a pinkish color. If the film has been spread too thickly at any point, this portion will present a greenish color.

4. Dry quickly between pieces of filter paper. It is very necessary that this drying be rapidly accomplished otherwise decolorization will occur.

5. Mount in balsam.

In properly stained specimens the polymorphonuclear neutrophilic leucocytes present dark blue nuclei and granules of a lilac

color with neutrophilic cytoplasm. The lymphocytes have dark blue or purplish-blue nuclei and light blue cytoplasm. The nuclei of the small lymphocytes stain more deeply than the nuclei of the large lymphocytes. At times a few blue granules (basophilic granulation) are observed in the cytoplasm of the lymphocytes, but occasionally red granules (acidophilic granulation) may be observed. The eosinophiles have blue nuclei with coarse granules of a bright red color and a bluish cytoplasm. Basophiles show usually a lilac nucleus with dark blue granules and a pale blue cytoplasm. The erythrocytes appear either pink or orange with stippling, if any is present, well brought out. Nucleated red cells present blue nuclei and cytoplasm which is slightly tinged with blue. Blood-platelets appear as rounded or rod shaped blue bodies with lilac granules. The processes of the platelets take a faint lilac stain. Myelocytes have darkly stained nuclei and bluish cytoplasm, with granules either lilac or dark-red in color depending upon the type of myelocyte. The malarial parasites show a blue body with one or more bright red nuclear structures (chromation). The age of the malarial organism seems to govern the exact color of the chromation.

One point which I recently noted is the fact that specimens stained by Wright's method begin to fade after one or two years. The nucleus of the leucocytes, which is at first usually dark blue, gradually fades becoming paler and paler in color. In addition the erythrocytes lose the bright pink or orange color and become a dirty pink or orange.

BOOK REVIEWS

Review of Niles' Work on Pellagra.—Pellagra, by George M. Niles, M. D., Professor of Gastroenterology and Therapeutics in the Atlanta School of Medicine, Atlanta, Georgia. Octavo of 253 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1912. Cloth, \$3.00 net.

A few years ago there were not a dozen physicians in the South who gave Pellagra a serious thought. Certainly there was none who devoted any of his time to devising means of treating and combatting it. But to-day every physician, not only of the South but of the entire country, is necessarily vitally interested in this dreaded disease. Because of this nation-wide interest, because pellagra threatens to become a national if not an international calamity, every practitioner should have close at hand a copy of this new work by Dr. Niles. It is the first book on the subject by an American author and is the first book in any language adequately covering treatment. And it does cover treatment adequately.

Every phase is considered: Dietetic, hygienic, hydro-therapeutic and medicinal.

The medical profession is indebted to Dr. Niles for this work. With it any medical man can place himself right in touch with the latest advances concerning this disease.

Diagnosis is presented in such a definite way that every case of pellagra can be readily recognized. This is especially so because Dr. Niles has taken great care to describe all the clinical manifestations of pellagra, thus preparing the general practitioner for any of the many complications commonly occurring.

As to be expected in all former works on pellagra, being by foreign authors, etiology and pathology has been presented only from the European side. Dr. Niles, however, not only presents the European views but also the newest theories and opinions of leading American authorities. The etiology is especially complete, all theories being presented impartially.

To sum up, Dr. Niles' book tells you definitely how to diagnose pellagra, how to recognize it when you meet it. It tells you the newest and best ways of treating pellagra. It tells you how to prevent its occurrence—how to combat its spread. It tells you all you want to know in connection with this disease. It certainly is a book every practitioner, particularly every practitioner in the South, should have and consult. We strongly recommend its purchase and use.

A Treatise on Tumors. For the use of Physicians and Surgeons. By Arthur E. Hertzler, M. D., of Kansas City, Mo., Assistant Professor of Surgery in the University of Kansas. Octavo. 728 pages, with 538 illustrations and 8 plates. Cloth, \$7.00, net; half Persian morocco, gilt top de luxe, \$9.00 net. Lea & Febiger, Publishers, Philadelphia and New York, 1912.

Approximately one-fourth of all surgical literature is devoted to tumors. This fact alone conveys some idea of the magnitude and importance of the subject, and should impress on the busy physician, surgeon and specialist the impossibility of even beginning to read this vast mass and the great difficulty of finding therein any particular information for which he may be in search. In the volume at hand, Dr. Hertzler has presented, in such proportion as his duties as teacher and consultant have shown to be most advisable, the experience of many years gained in the operating-room, the observations of laboratory study, and the information gathered from the literature. To make his volume one of maximum utility he has, in presenting the subject kept in mind the application of both the scientific viewpoint and clinical observation. The practical aspects have received strong emphasis. The volume is one which brings the general practitioner and surgeon into co-operation. It is sumptuously illustrated with original engravings and plates.

NAME THE BABIES.

During the first year of the operation of the Vital Statistics Law the chief difficulty to registrars in handling birth certificates was the matter of the babies' names. Without this the document is legal enough as far as it goes but not clear as to which child made its advent at such a time, and some injury may be worked in the future by this omission. We believe physicians hold the balance of power at this point and by studied effort can so educate and influence people that in a few years no Kentucky baby will be nameless longer than ten days. The doctor, particularly the family doctor—God bless him—holds the place of counselor and comforter in the homes of his patients. His coming brings assurance and his words are listened to with confidence from the oldest to the youngest in the household. We have in mind one of this type who joyfully tells the mother that if she does not select the name by his next visit, he will register the infant as "Peggy" or a similar unattractive name. This usually results in a prompt compliance with his request for a speedy settlement of this momentous question. And it is usually a momentous question, especially with the firstborn. If, however, it is explained that the Bureau of Vital Statistics is "Kentucky's Big Family Bible" and that this certificate with the baby's name inserted will become a legal record preserved by the State, insuring proof of its legitimacy, its age, its color and other vital facts on our record which have been overlooked for so long that we have to be reminded of the fact that as far as a legal record is concerned our forefathers were illegitimates and probably of variegated colors.

There can be no opposition to the operation

of this law if the doctors of the State will 'hit the nail on the head' with a few well-directed blows, which show that family history and future welfare of the child are at stake in getting a complete record of this event.

Will the doctors of the State, therefore, insist that babies be named at once and in all cases where they are forewarned of the coming event will they request the parents to select two names so that the baby may be labeled on the spot.

ENFORCEMENT OF HEALTH LAWS.

We republish an editorial from the *Courier-Journal*, of April 16th, which we feel sure will be of interest to all of our readers:

"A committee from the Lexington Board of Health recently made a trip to the East for the study of advanced methods of sanitation. In the course of the journey members of the committee secured copies of health ordinances in numerous cities with a view to the final preparation of a health code 'written out of the best of the experiences elsewhere and in full harmony with the State statutes to which city ordinances must comply.'

"The committee in its formal report makes the sensible observation that 'to the extent that the work of the health department is constructive, practical and considerate of the rights of the trade or individuals, with full fairness to all, just to such an extent is a firm basis established for putting the purposes of the law into effect.' The report adds:

"Every citizen is entitled to pure air, pure water, pure food and surroundings free from disease, and no dairyman, meat dealer or other food purveyor, tenement owner, factory-operator, corporation or individual is privileged to infringe in any manner upon these vital rights of the general public. On

the other hand, if the laws are practical and enforced with intelligence and fairness alike to all, there is no interest or individual, city or community that will not profit in money, greater labor efficiency, health and contentment, through the observance of those rules that are known to protect and promote the public health.'

"This is a very accurate and conservative summary of the problem of the enforcement of health laws. A committee which takes such a common sense view of the duty of a health department to the public and to the individual may be safely entrusted to the work of preparing a sanitary code. It is certainly true that practical health laws are for the benefit of all. There are some 'interests' which do not seem to understand this and there are others which, for reasons of their own, do not want to understand it. As between these classes and the general 'vital rights of the general public' the conscientious health officer should give the public the benefit of the doubt if he finds occasion for any hesitation in the performance of his duties."

HEALTH AND THE COUNCIL.

An editorial from the *Herald*, of the 19th inst., is published not only because of its real value but to show the great work being accomplished by the newspapers of Louisville:

"Wednesday night's session of the City Council was about as unsatisfactory an affair as could well be imagined. As had been foreshadowed by previous expressions of stupidity and unwarranted obdurateness, the Board of Aldermen flatly refused to pass the quarantine ordinance as framed by the Health Department. Instead, they included spinal meningitis in a list of diseases named in an old ordinance of several years standing. It had been hoped that two weeks' deliberation, a communication from the Mayor, and pressure by the Commercial Club and various women's organizations, would avail to bring the aldermen around to an intelligent attitude toward the measure. That it did not do so brings nothing but discredit to the board's intelligence and sense of public service.

"If the councilmen concur in the measure passed by the Board of Aldermen, the needs of the moment as regards the meningitis campaign are satisfied. But this is only one of the contests that the Health Department is waging. The Department wants, and should have, discretionary authority to deal as it sees fit with all transmissible diseases. Under the ordinance, as framed and presented, this authority would have been given. Under the ordinance as passed, on the other hand, the Department has marked off for it just what diseases it may placard and quarantine. Men-

ingitis has been added to the list, thanks to a battle of several weeks' duration. But cholera has not, nor has yellow fever nor bubonic plague, nor a host of others. We are not expecting an immediate epidemic of meningitis. As the matter stands now, the appearance of any disease not included in the list would necessitate an amendment to the ordinance before the Health Department could perform its functions in protecting the city's health. The contemplation of this condition is enough to point the necessity for continuing the campaign until the more comprehensive ordinance requested by the Health Department is passed.

"The Health Committee of the Council is making quite as inglorious a record as that of the Board of Aldermen. The indifference and positive opposition that its members are showing to the proposed fly-screening ordinance cannot be condoned on any score. Two members of the committee failed to keep an engagement with health officers and several women on Monday when it was proposed to discuss the merits of the ordinance, and the meeting was adjourned without results. And on Monday night a similar attitude was shown by the absence of every member of the committee from another meeting scheduled for the same purpose.

"This ordinance, which provides for the screening of all garbage cans, vaults and refuse receptacles, would reduce more than any conceivable contrivance the danger incident to flies during the spring and summer months. It should meet with favorable action at the hands of the council without delay."

THE PUBLIC HEALTH.

The following editorial from the *Louisville Post* of the 13th inst., is an excellent example of the appreciation of work for the preservation of the public health now going along in Kentucky:

"The Evening Post received a letter from 'Constant Reader,' asking if in our judgment, the public library should not be closed in order to check the spread of disease 'due to unfumigated books?'

"The Evening Post has had a theory that science in the discovery of the germ of disease has done much to destroy fear, and fear is the very worst disease that can afflict the public mind.

"But there are a number of persons whose fears are accentuated by the apprehension of floating germs, and they find them everywhere, at all times, and under all conditions.

"The Evening Post believes that health matters concerning the Public Library, the Public Schools, and all other gatherings, had best be left to the health officers. It is our

judgment that these gentlemen are doing all that science justifies them in doing, and that probably they are going a little beyond the absolute line of security in order to allay fear that cannot be allayed by any device whatever.

"It can be remarked incidentally that a week ago the children's department of the library was closed as a matter of extra precaution, but it has not been deemed necessary to close the library to the use of intelligent adults.

"Our belief is that there is no possibility of transmitting the germ of spinal meningitis through the unfumigated books at the library. We believe that the germ of scarlet fever is perhaps the most long-lived and persistent of all germs; but there is little or no scarlet fever in this city, and we do not imagine that there is any danger from contagion of meningitis through the books.

"There have been a few instances in which more than one case of this disease occurred in one family, but these occurred at one and the same time, showing that both victims had been infected by the same causes. Little is known about the method of transmission, but the general belief is that it is transmitted through the atmosphere to some susceptible body; whereas, other persons in contact with the victims pass unharmed. The theory is that they are immune; that they furnish no opening to the germ, but that they may themselves, in expelling the germ, through sneezing, coughing or expectoration, convey the germ to other susceptible people.

"It seems hardly probable that the germ of spinal meningitis could be carried in the clothing or any other way save through the atmosphere, and that by the means indicated.

"There have been more cases of spinal meningitis in Louisville this year than for several years, but there have been no large number of cases, though there have been a large number of deaths in proportion to the cases. The reason for this large mortality is that the trouble is difficult to diagnose until it is too late to apply the heroic serum treatment.

"It is further to be considered that many of the cases called meningitis this year were called gripe or pneumonia or some other kindred disease last year.

"The Evening Post is not an alarmist, and it does not suppress the news. It is giving all the verified facts, and it is not making itself a common carrier for alarming reports which, when investigated, are found to be groundless. The Health Department is dealing with perfect frankness with the people, and the newspapers, as far as we have observed, are following a like policy of candor.

"Instead of advising the Health Department as to what institutions should be closed, we would advise our friends to follow the

ordinary rules of precaution, of self-protection, and above all things to cultivate that feeling of confidence and cheerfulness that is the best resistance to disease of any character at any time."

COMPLIMENT TO THE LOUISVILLE CITY BOARD.

It is with especial pleasure that we reprint the attached compliment to the City Board of Health of Louisville. Dr. Grant's work has been particularly effective:

"E. E. Rittenhouse, conservation commissioner of the Equitable Life Assurance Society, is in Louisville, to-day, the guest of Henry J. Powell, State agent of the same company. Mr. Rittenhouse is completing a tour of the South for the purpose of consulting with the heads of the Health Departments of the large cities of the South and the medical officers of the various States, concerning methods for the conservation of human life.

"Mr. Rittenhouse was in conference to-day with Dr. Ed Grant, Health Officer of the city of Louisville. In an interview Mr. Rittenhouse said:

"The movement for the conservation of human life has assumed nation-wide proportions. The activities of the public health departments have doubled in the past five years. The Equitable Life Assurance Society has joined in this great movement, not only because a reduction in death rates reduces the cost of insurance to policyholders, but because it wants to use its influence and help in reducing sickness and life waste in this country.

"The death rate in this country has been reduced 25 per cent. in thirty years.

"It is entirely within the limits of possibility for Louisville to cut its death rate in two in the next thirty years. You have certainly the right spirit and have made the right start by the building of trunk-line sewers. You have also made an extraordinary advance in providing the new million-dollar hospital, which is now being constructed, and which will take rank among the greatest institutions of its kind in the country.

"I have visited many cities, as we watch the mortality closely, and none are making better progress than Louisville in the direction of life conservation. This is of vital importance, because there are about 1,500 people dying in Louisville annually from preventable cause."

A NEW DICTIONARY.

We wish to call the special attention of our readers to the opportunity of getting a first-class dictionary in accordance with the terms described in the advertisement, on page XX of the April 1st issue. The Editor has taken advantage of it and this dictionary is really worth while, being all in one volume and containing practically all of the words in the English language. It will be invaluable on every busy man's desk.

THE N. F. NOT A THERAPEUTIC NECESSITY.

The American Pharmaceutical Association, which publishes the National Formulary bases the book on "pharmaceutic necessity" and not on "therapeutic utility"—that is, it admits those articles for which the pharmacist believes there is a demand, no matter whether such preparation is of therapeutic value or not. So also, a voting majority of the Committee that issues the United States Pharmacopoeia insists that the book shall contain those articles for which there is demand no matter from whence this demand comes and no matter whether the drug be valuable or worthless. In view of the admitted scope of these books it is somewhat difficult to understand how the National Association of Retail Druggists has the hardihood to argue that physicians should use *all* U. S. P. and N. F. preparations just because they are of the U. S. P. and in the N. F. And yet this is the tenor of the "U. S. P. and N. F. Propaganda" of this association of druggists.

Recently the *Journal A. M. A.* warned physicians that this propaganda was likely to result only in weaning physicians away from proprietary nostrums to become addicted to the equally unscientific habit of prescribing unscientifically the shot-gun mixtures of the U. S. P. and N. F. In view of the active "propaganda campaign" that is being waged just at present, we quote the following from an article in the *Journal of the Missouri State Medical Association* (February, 1912, p. 322) in which it is pointed out that the National Formulary, while useful as a book of convenient formulas, is not a book which the physician should in any way consider a therapeutic necessity. The physician who can get along without it is to be congratulated. The many complex formulas contained in it are a credit neither to the pharmacists who devised them nor to the physicians who prescribe them. In these days of scientific thought, when physicians want to know the effect produced by each drug given and hence abstain from prescribing the old, hopeless con-

fusions formerly in vogue, there is little need for the most of the ready-made things in the book."

NOSTRUM ADVERTISING IN THE RELIGIOUS PRESS.

No class of publications has made greater progress, says the *Journal A. M. A.*, (March 23, 1912, p. 864), in censoring its advertising than the religious journals. Four or five years ago, the various church publications fairly reeked with advertisements of nostrums of the most fraudulent and vicious kinds. A wonderful house-cleaning has taken place in the past half-decade, and most religious journals of the better class have dissolved their previous coalition with the "great American fraud." Here and there, of course, are to be found church papers that are still willing to share the blood-money of quackery for the sake of increasing their revenue. One of this class appears to be the *Northern Christian Advocate* which carries advertisements for the notorious humbug Oxypathor. Oxypathor is the name applied to what was formerly known as the Oxygenator one of the numerous devices sold in the exploitation of what has been called "gas-pipe therapy." The Oxypathor consists of two flexible cords attached to a piece of nickel-plated piping filled with an inert mixture of clay and cobalt and sold as a "cure" for diphtheria and nearly every other disease. It has just as much curative value as a tomato-can with a piece of string tied to it.

It is but fair to say that while the *Northern Christian Advocate* is a Methodist publication, it is not owned by the Methodist church, but by a number of ministers. Apparently, there is the same commercial domination of what may be called the independent religious press as that which at present afflicts a large proportion of the "independent" medical press. The evil in both cases will doubtless continue until the intelligent subscribers refuse longer to be *particeps criminis* with the publisher in perpetuating fraud.

DEATH OF DR. RUSSELL BROUGHTON

We note with regret the death, at Rockford, Illinois, on April 4th, of Dr. Russell Broughton, familiarly known to the physicians of Kentucky as the physician in charge of one of the best sanitariums for nervous diseases in this country. Our readers will be glad to know that the Sanitarium will continue to be conducted by Dr. G. A. Weirick, Dr. Broughton's successor. The profession can ill afford to lose such a man as Dr. Broughton.

SCIENTIFIC EDITORIALS.

COMMERCIALISM: A RUDE AWAKENING.

Babylon was in a blaze of glory, haughty and high spirited in its pride and wickedness; proud of its power, its beauty, its marvelous hanging gardens, one of the seven wonders of the ancient world. Belshazzar, the king, the last of the Babylonian dynasty, himself an usurper, made a great feast, eating and drinking out of the golden and silver vessels, taken from the temple of Jerusalem. Great was the feast, many were the slaves waiting upon the people, many were the princes' wives and concubines that sat about the festive board and "drank in them." Belshazzar trusted to his walls and to his marvelous fortifications, but in the hour of his confidence and in the hour of his power, "came forth fingers of a man's hand, and wrote over against the candle stick, upon the plastering of the wall, of the King's palace, and the King saw the part of the hand that wrote," and Potentate though he was, fear entered into his heart, his knees smote together, and he hastily summoned about him his astrologers, his Chaldeans and his soothsayers, but none could read the writing on the wall. Daniel was sent for; "Mene, mene, teckel, upharsin," and Daniel stretched forth his hand, and said, "And, thou, oh son of Nebuchadnezzar, has not humbled thy heart, but God hath numbered thy kingdom, and finished it; thou art weighed and found wanting, and thy kingdom is divided"; and almost as the prophetic words fell from the mouth of the great disciple of the Divine Will, Darius, the Mede, marched through the open gates of the city and slew Belshazzar in all his glory.

The story of ancient Babylon may in analogy be applied to things more modern; perhaps it is suggestive; perhaps "the moving hand having writ, moves on" from Belshazzar's time to ours, and perhaps there is upon our wall, over against the candle stick, in the brilliant light another "Mene, mene, teckel, upharsin," one that may possibly, in the very near future bear some of the same kind of fruit as was borne to Belshazzar upon that memorable night before the days of Christ. And what, may I ask, is the interpretation of our Daniel, of the writing hand? It is, in my opinion, the powerful and reforming force of publicity.

In Pearson's for September, 1911, and March, 1912, Arno Dorsch, writing under the titles of "Farce of Medical Ethics," and "Too Many Doctors," says some very hard things concerning the medical fraternity and of the

necessity of giving them the widest publicity.

My object in reviewing these attacks is not to enter into the so-called "moral side of the question;" I say "so-called" because morals do not signify a question of right and wrong, but really "custom;" and it is notorious that what may be moral in one generation may be immoral in another, that is to say, the "customs" may be different.

My object is to point to what, in my opinion, is a serious menace and danger to the medical profession. These articles, giving the widest publicity to some of the defects in our present system, will have an undermining effect upon the confidence reposed in us as a medical body. I believe that the majority of real doctors do not indulge in the practices mentioned; that they, as a body, give more freely of all that they know than any other body of professional men in existence and that they stand, as a rule, for the highest principles in public, private and professional life; that they are more liberal with their services to the poor and poverty stricken than any other body of men; that they give more freely of their sympathy, consideration and emotional nature and that many live a life of self abnegation true to the highest ideals.

Dorsch attacks the medical school and it cannot be gainsaid that his statement that we have too many doctors on our hands who have not had a fair chance to learn their profession, is absolutely true, and this he upholds because Mr. Abraham Flexner has stated that "of the 154 schools now *grinding out graduates*, he could see an excuse for only 31; of these, only 26 are in the United States." We might paraphrase Mr. Flexner's comment and say that in many cases, public health would be better cared for if all the vacancies remained unfilled for a decade to come." These schools he said, lacked proper equipment and money to buy it; lack of ideals; self aggrandizement of faculty and were being conducted purely and simply as money-making institutions. Certainly his arraignment is severe enough to make every young man aspiring to enter the already overcrowded profession cautious as to the selection of his profession, his school and his vocation. Indeed in these strenuous times, nay, very hard times, it is an open question as to whether a young man is justified in entering the profession of medicine. It is oftentimes a courage born of ignorance. The severest arraignment is on the fee-splitting between family physician, surgeon and specialist. It would indeed be a pleasure to refute his contentions, but they cannot be refuted, for it is doubtless true, that many doctors have such a hard time making a living that they have to split fees or something else. He

comments upon the taking of commissions by certain doctors on prescriptions filled at certain drug stores. While in some cases of large fees, the taking of part by the humble and estimable family physician without the knowledge of the patient may be condoned, the accepting of a drug store rebate is nothing more than *petit larceny*, and is beneath a profession who chooses to consider their fees as an *honorarium*. He advises each and every doctor to print his own prescription blank; a rule that I have followed for twenty years. There is no question but what the commission accepting from druggists and the division of fees between doctors will have to stop. It is not going to be left to the profession to clean its own Augean Stables, but the hand writing on the wall is plainly visible, and it takes no medical Daniel to tell the profession that such practices and such methods cannot long survive the lime light of publicity, nor the cold logic of the business man.

In the end, I believe things will be better. The family physician as well as the surgeon or specialist is entitled to a just and reasonable compensation for his services and he should demand it. There is no physician, surgeon or specialist that is worthy of the name that will not back him up in his rights, in his demand for recognition and compensation; but this must be granted with hands above the table and with an ungummed deck of cards; it must be a *square* deal, between *all parties concerned* and where this is carried out, not only will it in the end be better for the family physician, but better for the consultant, surgeon or specialist and in the long run, better for the patient. Self respect, begets respect from others, and honesty of purpose and openness of action will insure that respect, that friendship and that close communion that should always exist between doctors and patients.

CURRAN POPE.

A MEAD OF PRAISE.

Anent my editorial in reference to the present tendency toward commercialism in the medical profession; a fresh addition to which has appeared from the pen of Dr. Reed, of Cincinnati, in the last issue of *Pearson's*. It becomes a pleasant matter to regard some extremely kind wishes and appreciation spoken in the profession's behalf.

The prayer, which follows is from the pen of Walter Rauschenbusch, and appeared in the *Volunteers Gazette*, the official organ of the volunteers of America. Mr. Rauschenbusch is unusually gifted along this line of writing, and his "prayers" have been a source of very pleasant reading to me. It is therefore with great pleasure that I recommend to my professional brethren, not alone the

prayer, but the beautiful ideas contained therein, as a light that might lead us kindly to further and better endeavors. We can but express our gratitude and appreciation to the author.

"We praise Thee, O God, for our friends the Doctors and Nurses, who seek the healing of our bodies. We bless Thee for their gentleness and patience, for their knowledge and skill. We remember the hours of our suffering when they brought relief, and the days of our fear and anguish at the bedside of our dear ones, when they came as ministers of Thee. May we reward their fidelity and devotion by our loving gratitude, and do Thou uphold them by the satisfaction of work done well.

"We rejoice in the tireless daring with which some are now tracking the slayers of mankind by the white light of science. Grant that under their teaching we may grapple with the sins which have ever dealt death to the race, and that we may so order the life of our communities that none may be doomed to an untimely death for lack of simple gifts which Thou has given in abundance. Make Thou our doctors the prophets and soldier of Thy Kingdom, which is the reign of cleanliness and self-restraint, and the dominion of health and joyous saving.

"In their whole profession, strengthen the consciousness that their calling is holy and that they, too, are disciples of the saving Christ. May they never through the pressure of need or ambition surrender the sense of a Divine mission and become hirelings who serve only for money. Make them doubly faithful in the service of the poor who need their help most sorely, and may the children of the working man be as precious to them as the children of the rich. Though they deal with the frail body of man, may they have an abiding sense of the eternal value of the life residing in it, that by Thy call of faith and hope they then may summon to their aid the powers of Thy all-pervading life."

CURRAN POPE.

NOT UNGRATEFUL, NOT UNMINDFUL.

"How sharper than a serpent's tooth, it is To have a thankless child."

—Shakespeare, King Lear, Act I, Sc. 4.

The statement of the great Bard of Avon is likewise applicable to-day to the position held by the good and faithful public servant for there are indeed many who fail to appreciate to its full, the unending labor and the ability required to carry out those endeavors that have for their object the benefit of the public at large. Appreciation seems to come only at times when a spectacular exhibition holds the public eye, when something meteoric in its

course lights the horizon and calls attention to the particular luminary; the laborer in the dark rarely ever gets sufficient credit for his work. Whenever an individual devotes his abilities and life to a work in favor of right, justice and truth, he is sure to meet with strong opposition from all the powers of darkness. These heap upon him every calumny possible, and the man that interferes with the powers of "Big Business," the minions of avarice, the quack, the patent drug man, the abortionist, and the *discontented*, opposes a formidable foe, full of power and is liable to be subjected to most unjust criticism and to suffer a penalty for his acts.

"Injustice swift, erect and unconfined

Sweeps the wide earth and tramples o'er mankind."

—Homer, Iliad, Book IX.

This is a day of a battle of individuals against powerful aggregations, a great fight of right against wrong, of the people against the interests, a fight to a finish, bare knuckles and London Prize Ring Rules.

No man to-day is safe from attack who is in public life and in the lime light; no work is too good to escape censure.

"He that doeth public good for multitudes, finds few are truly grateful."—Massinger. Lately the medical profession through its State Board has been under investigation, and it is indeed to the profession, a source of great gratification that not alone has the Board been vindicated, but that it has come through clean and is in a position to-day to carry forward its great work for the people of the state of Kentucky. The public press tells us the middle of this month that Kentucky has made a most excellent record in its vital statistics registration, and the profession is now to be congratulated upon at last being in the registration area, an area of modern medical civilization.

It cannot, however, be said that the Kentucky profession were unmindful of its State Board work, nor of the long labors and useful life of its secretary, nor can the charge be laid to their door of being ungrateful or guilty of injustice. They have indeed disproved in this instance, Shakespeare's saying,

"Blow, blow thou Winter wind,

Thou art not so unkind as man's ingratitude."

—As You Like It, Act II, Sc. 7.

The Kentucky profession has its idols and hopes the good work will ever go on under able administrative hands.

The profession stands unalterably in the van of medical progress, desiring the safety and health of the public, pure food, vital statistics and the clean and honest administration of all health propositions.

We can, in conclusion, truly say that we are proud to stand back of our State Board, and that the intelligence of the entire profession is with them in their work and that we expect medically to reiterate the motto of the grand old Commonwealth of Kentucky,

"United we stand and divided we fall."

CURRAN POPE.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicine. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A., Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters, tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A., Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

RELIABLE MEDICINES.

Articles found eligible by the Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies."

CORNUTOL is a biologically tested liquid extract of ergot. Dose, hypodermically, 0.65 to 2 cc. (10 to 30 minims); by the mouth 0.65 to 4 cc. (10 to 60 minims). The date of testing appears on each package. Cornutol is put up in 1 ounce vials and in ampuls, each containing cornutol 2 cc. (30 minims). H. K. Mulford Co., Philadelphia. —(*Jour. A. M. A.*, March 9, 1912, p. 701).

DIGITALIN is a biologically and chemically standardized, fat-free tincture of digitalis, corresponding in drug strength to tincture of digitalis, U. S. P. Dose, 0.3 to 1 cc. (5 to 15 minims). The date of testing appears on each package. H. K. Mulford Co., Philadelphia. —(*Jour. A. M. A.*, March 9, 1912, p. 701).

ERCOPIX is methyl-codeine bromide, $C_{18}H_{21}O_3N(CH_3) Br$. It is easily soluble in water. It corresponds to 80 per cent. of codeine and to its own weight of codeine sulphate. It is said to be useful as a sedative as a substitute for codeine, especially in cough, where its action sometimes favors secretion. Dose, 0.06 gm. (1 grain).

EUCODIN is also marketed in the form of tablets each tablet containing eucodin 0.05 gm. (5-6 grain). Riedel & Co., New York. —(*Jour. A. M. A.*, March 16, 1912, p. 780).

*The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Ave., Chicago.

Euscorol is optically inactive scopolamine hydrobromide $C_{17}H_{21}O_4N.HBr$. It is easily soluble in water and alcohol. It closely resembles the official scopolamine hydrobromide in its physical, chemical and pharmacologic properties. It is claimed to have a milder action because of the absence of other alkaloids said to be contained in the natural scopolamine hydrobromide. Riedel & Co., New York.—(*Jour. A. M. A.*, March 16, 1912, p. 780).

PHARMACEUTICAL PREPARATIONS OF ACCEPTED ARTICLES.

Tablets, Oxyntin with Pepsin, each containing oxyntin 3 gm. (5 grains) and pepsin equivalent to pepsin, U. S. P., 1 grain.

Capsules, Oxyntin with Nux Vomica, each containing oxyntin .3 gm. (5 grains) and nux vomica equivalent to tincture nux vomica 0.33 cc. (5 minims).

Capsules of Holadin, Bile Salts and Phenolphthalein, each containing holadin 0.13 gm. (2 grains), bile salts, Fairchild 0.03 gm. (1-2 grain), phenolphthalein 0.065 g m. (1 grain).

Capsules of Holadin, Succinate of Soda and Bile Salts, each containing holadin, 0.20 gm. (3 grains), sodium succinate exsiccated 0.20 gm. (3 grains) and bile salts, Fairchild 0.03 gm. (1-2 grain).

Capsules of Bile Salts, Succinate of Soda and Phenolphthalein, each containing bile salts, Fairchild 0.065 gm. (1 grain), sodium succinate, exsiccated 0.20 gm. (3 grains), and phenolphthalein 0.03 gm. (1-2 grain).—(*Jour. A. M. A.*, March 16, 1912, p. 780).

RELIABILITY OF DIGITALIS AND ERGOT PREPARATIONS.—Recent investigations by Edmunde and Hale of digitalis and ergot preparations, claimed to have been standardized biologically, suggested that the manufacturers had not used the care and skill in making the product which the advertising claims would lead one to expect. One manufacturer, the H. K. Mulford Company, has met these serious charges and having instituted the reforms suggested by the examination has secured the acceptance of its preparations, Cornutol and Digital, for inclusion with New and Nonofficial Remedies.—(*Jour. A. M. A.*, March 9, 1912, p. 705).

SQUIBB'S THOREMEDIN (THORADIN) EXPOSED.—This "cancer cure" (claimed to depend for its activity on radio-active thorium is shown by analysis in the A. M. A. Chemical Laboratory to contain 35 per cent. of concentrated sulphuric acid. Dr. W. A. Pusey points out that the activity of the cancer paste depends on the generally discarded and discredited cauterant sulphuric acid and deplores the fact that the honored name of E. R. Squibb and Sons should have become connected with

this vicious nostrum.—(*Jour. A. M. A.* March 9, 1912, p. 716).

SULPHURRO.—Sulphurro is put out by the C. M. C. Stewart Sulphur Company, Inc., Seattle, Washington. Examination in the A. M. A. Chemical Laboratory showed that it, like sulphume and other "liquid sulphur" preparations, is a solution of calcium sulphide such as is obtained when sulphur lime and water are boiled together. The foul smelling liquid is recommended to the public for the treatment of rheumatism, asthma, goiter, eczema, dyspepsia and all diseases of the stomach, bowels, kidney, skin and blood. Its use as a rectal enema, a vaginal douche or as an eye wash is also recommended.—(*Jour. A. M. A.*, March 9, 1912, p. 719).

REFORM IN MEDICINES.

DEFINITION OF NON-PROPRIETARY MIXTURES.

—To distinguish between mixtures that are not admitted to New and Nonofficial Remedies because they are non-proprietary and hence without the scope of the book from proprietaries that are not in the book because they are ineligible, the following definition of proprietary mixtures is given: "A mixture will be considered as proprietary, and therefore requiring consideration by the Council and admission to the book or appendix, if it contains any proprietary article, if it is marketed under a name which is in any way protected or if its manufacturer claims for it any unusual therapeutic qualities."—(*Jour. A. M. A.*, March 9, 1912, p. 719).

STERILIZATION OF COCAIN SOLUTIONS.—While it is generally believed that cocaine solutions may not be rendered sterile by boiling, experiments have demonstrated that under ordinary conditions cocaine solutions can be boiled without serious decomposition.—(*Jour. A. M. A.*, March 9, 1912, p. 721).

THYROID AND MORAL RESPONSIBILITY.—A plea of partial irresponsibility on account of thyroidism (induced by taking thyroid tablets in excess) was made in a London police court. This is another illustration of the risks in health incurred by those who indulge too freely in thyroid or in some of the "anti-fat remedies" containing it.—(*Jour. A. M. A.*, March 16, 1912, p. 787).

MARJORIE HAMILTON'S OBESITY CURE.—This is claimed to be a dietless and drugless system for the treatment of obesity. The advertising booklet sent out by Marjorie Hamilton, Denver, Colo., prescribes, however, a system of dieting and as a means of revenue to the promoter prescribes frequent baths with "Healthstone-Obesity Bath Powder," sold at \$2.00 a pound, to be applied to "the fat parts or whole body twice daily." Marjorie Hamilton's bath powder was examined in the chem-

ical Laboratory of the American Medical Association and found to consist chiefly of sodium carbonate with smaller amounts of magnesium sulphate, potassium nitrate and possibly sodium sulphate.—(*Jour. A. M. A.*, March 16, 1912, p. 798).

PHENACETIN AND ACETPHENETIDIN.—While at one time the product sold as phenacetin was protected by patent and the name trademarked now, that the patent has expired, the product as well as the name is non-proprietary. Although it is official in the pharmacopoeia as acetphenetidin, physicians generally prescribe it by the formerly proprietary name phenacetin. As the product sold under the name phenacetin demands a price as much as five times that asked for acetphenetidin in the A. M. A. Chemical Laboratory determined the purity of the market supply, of acetphenetidin and of phenacetin and found both equally pure. Inasmuch, therefore, as acetphenetidin complies with all the pharmacopoeial requirements as to identity and purity, in just the same way as phenacetin, physicians need not hesitate in using the title of the U. S. P. "acetphenetidin" when prescribing this product.—(*Jour. A. M. A.*, March 16, 1912, p. 801).

CHINOSOL.—Although chinisol is now recognized by the Council on Pharmacy and Chemistry and is described in New and Non-official Remedies, physicians, so the Chinisol Co., complains, are inclined to ignore the product, because at one time claims made for it were criticised in a report of the Council.—(*Jour. A. M. A.*, March 16, 1912, p. 804).

TINCTURE OF IRON AND THE TEETH.—Preparations claiming to contain tincture of ferric chloride in a form that will not effect the teeth are impossibilities. It may be assumed that if such a preparation does not injure the teeth when given in ordinary dilution, it does not contain chloride of iron. If, therefore, one desires to use the chloride or iron for its local effects on the throat, the stomach or the intestines, it is necessary to give it through a tube or largely diluted, in order to prevent injury to the teeth.—(*Jour. A. M. A.*, March 16, 1912, p. 805).

CRESOLENE.—Cresolene, or Vapo-Cresolene, according to the A. M. A. Chemical Laboratory is essentially cresol and corresponds in every respect to cresol, U. S. P.—(*Jour. A. M. A.*, March 16, 1912, p. 806).

DIABETIC FOODS.—While much has been written to show that gluten flours and gluten foods are unreliable and unsatisfactory as food for diabetics nevertheless a study of the markets shows that there must be a steady and even growing demand for these products, if the increasing number of "brands" offered for sale may be taken as an index of the busi-

ness. The entirely unsatisfactory "standard" established by the government and accordingly adopted by various boards is plainly responsible in great measure for the unfortunate situation that now exists. The United States standard for gluten flour calls for a protein content of only about 40 per cent, leaving the unfortunate possibility of having a preparation which is one-half starch marketed in conformity with legal requirements. A recent series of analyses of goods sold as gluten preparations in the state of Connecticut showed that most of them exceed the requirements of the standard; yet these foods, the products of the Pure Gluten Food Co., The Health Food Co., Johnson Educator Food Co., D. M. Welch & Son, and the Battle Creek Sanatorium Food Co., contains from 27 to 68.85 per cent, starch. It is suggested that a statement of starch content, on the label of each product, be made compulsory.—(*Rep. Conn. Agric., Expr. Sta.*, 1911, Part II, p. 134).

WHAT'S THE MATTER WITH MICHIGAN?—"Professor Samuels," of eye water fame, finding things uncomfortable in Kansas announces his proposed removal to Michigan, a state where quacks are least liable to inspection on the part of officials. Michigan, it appears, has as many mail-order medical fakes of a vicious and fraudulent character as can be found in any other three states in the Union, irrespective of population and one wonders what peculiar influence protects swindlers in this state.—(*Jour. A. M. A.*, March 23, 1912, p. 863).

"BOOST FOR REXALL."—The United Drug Company whose products are sold under the general trade mark name "Rexall" is a co-operative patent-medicine concern like the American Druggist Syndicate, "A. D. S.," composed of druggists who, not content with the profits derived from the sale of patent-medicines, have engaged in their manufacture as well. Like other patent medicine manufacturers this concern, because of the more stringent state and federal laws governing the sale of "patent-medicines" in the United States has decided to extend its operations to England which is fast becoming the haven of patent-medicine promoters.—(*Jour. A. M. A.*, March 23, 1912, p. 876).

THE BRANERMAN REMEDY COMPANY.—The Dr. Brainerman Remedy Company is a mail-order medical fake of Kansas City, exploiting a "cure for deafness" against which a fraud order was issued by the Post-Office Department. It has received a final knockout blow through a recent decision of the United States Circuit Court for the western district of Missouri which denied an injunction against the fraud order issued by the Postmaster-General. An interesting feature of the complainant's

bill of equity asking for the restraining order against the Kansas City postmaster was the allegation that the action of the Postmaster-General was the result of a conspiracy involving the American Medical Association, the Jackson County (Mo.) Medical Association and a number of doctors of Kansas City, as well as the attorneys for the government and the United States post-office inspector. This seems to be becoming the favorite defense of the quack, the faker and the nostrum-vender, when they are brought to book for their fraudulent methods—claiming conspiracy with others on the part of the American Medical Association, the great "medical trust," which seeks to destroy a lot of innocent but enterprising gentlemen who are only seeking to benefit the people and incidentally to earn an honest dollar.—(*Jour. A. M. A.*, March 23, 1912, p. 877).

THE BRITISH PHARMACEUTICAL CODEX.—This book combines the features of the American dispensaries and of the National Formulary. The work bears evidence of having been critically written and of having been revised to include recent pharmaceutical investigations and thus is much superior to the dispensaries published in this country and it should, therefore, be of correspondingly greater value to physicians. While the formulas given are many and excellent, and their intelligent use by physicians in place of proprietary remedies represents a step forward in therapeutics, the physician who uses the codex should not accede to the evident intent of its compilers to favor the employment of critical prescribing.—(*Jour. A. M. A.*, March 23, 1912, p. 886).

NATURE'S CREATION.—A peep behind the scenes as regards the exploitation of patent medicines is given through the falling-out of the exploiters of Nature's Creation. This nostrum was first sold to the public as a cure for syphilis but later became a "consumption cure." The chief promoters, Mrs. J. M. Reynolds and Mr. H. W. Campbell, have had a falling-out and Campbell has taken the matter into court. The sordid details now brought out, it is hoped, will demonstrate to the public the fraudulent nature of the stuff.—(*Jour. A. M. A.*, March 30, 1912, p. 953).

OBJECTIONABLE PROPRIETARY NAMES.—In an address to manufacturers the Council on Pharmacy and Chemistry shows that it is possible to provide medicines with names descriptive of their composition and that the interests of both the manufacturer and the consumer, the physician and his patient, can be sufficiently safeguarded if to the descriptive name of an article there be appended a distinctive word, syllable, initial or sign that shall identify its manufacturer. The feasibility

of coining proprietary names that shall indicate the important constituents of a remedy is shown by illustrations taken from "N. N. R." The objectionableness of names which suggest the use of a remedy to the public is discussed and it is also pointed out that names suggestive to physicians are objectionable because there is a tendency that physicians will base their use of the remedy on the name without giving due consideration to the condition and symptoms of the patient. Since therapeutically suggestive titles have been applied to proprietary medicines without any intention of appealing to the public and since it is difficult to change a name once established the Council has decided to make no objection to such titles if they are already in use provided they are not liable to lead to the use of a remedy by the public.—(*Jour. A. M. A.*, March 30, 1912, p. 953).

WINSLOW'S SOOTHING SYRUP.—Being held injurious to life the sale and advertising of Mrs. Winslow's Soothing Syrup has been prohibited in New South Wales, Australia.—(*Jour. A. M. A.*, March 30, 1912, p. 954).

DIASTASE PREPARATIONS UNSTABLE.—A discussion at a meeting of the Societe de Therapeutique de Paris called attention to the instability of diastase, particularly in liquid preparations. Speakers emphasized the necessity of using only recently-made malt preparations in therapeutics if the enzyme action be desired.—(*Jour. A. M. A.*, March 30, 1912, p. 954).

FORMICIN is formaldehyde-acetamide, $\text{CH}_2\text{C}_6\text{H}_4\text{N}(\text{CH}_3)\text{OH}$, a molecular compound of formaldehyde and acetamide. It is a thick syrupy, water-soluble liquid, having a faint formaldehyde-like odor and a slightly acid, bitter taste. Solutions of formicin liberate formaldehyde gradually at body temperature, and thus exert an antiseptic action. Formicin solutions are employed as injections into tuberculous and non-tuberculous joints, tissues and abscesses. Kalle & Co., New York.—(*Jour. A. M. A.*, April 6, 1912, p. 1014).

IODO-CASEIN is a compound of iodine with milk casein, containing about 18 per cent. of iodine in organic combination. It is a powder almost odorless and tasteless and insoluble in water. It is said to undergo practically no change in the stomach, but to be quickly digested and absorbed in the form of soluble iodides in the intestines. Dose, 0.3 to 1.3 gm. (5 to 20 grains). Iodo-Casein is also marketed in the form of tablets each containing 0.5 gm. (2 1/2 grains) and 0.3 gm. (5 grains) iodo-casein. H. K. Mulford Co., Philadelphia.—(*Jour. A. M. A.*, April 6, 1912, p. 1014).

A GOOD EXAMPLE.—Having presented a member with a copy of "Nostrums and Quackery" the Los Angeles County Medical Society

now presents a copy of "New and Non-official Remedies, 1912," to each member. It is suggested that with the possible exception of those physicians whose confidence in their own good judgment is equaled only by their child-like faith in the statements of proprietary manufacturers that a copy of the book ought to be in the hands of every physician who prescribes.—(*Jour. A. M. A.*, April 6, 1912, p. 1021).

ZYMOTOID.—Dr. Arnold's Zymotoid, a non-train manufactured by Arnold's Zymotoid Company, Rockford, Ill., is a fraud of the Lignozone-Oxytonic-Septicide type. The A. M. A. Chemical Laboratory reports that the composition of Zymotoid was found to be: boric acid ((H_3BO_3) 0.637 gm., sulphur dioxide (SO_2) 0.129 gm., sulphuric acid (H_2SO_4) 0.048 gm., potassium nitrate, a trace, unidentified organic matter, a trace, and water (by difference) to make 100 c.c. The analysis shows that but for the presence of boric acid the composition of Zymotoid is similar to other fraudulent "microbe killers."—(*Jour. A. M. A.*, April 6, 1912, p. 1030).

HAMLIN'S WIZARD OIL.—From published formulas it appears that Hamlin's Wizard Oil is a variable mixture containing spirit of camphor, spirit of ammonia, chloroform, oil of sassafras, oil of cloves, oil of turpentine and alcohol. Linaments of this kind should be considered as belonging to the past.—(*Jour. A. M. A.*, April 6, 1912, p. 1033).

ORIGINAL ARTICLES

PELLAGRA.*

By M. W. STEELE, Corbin.

In dealing briefly with this subject, I shall confine myself principally to observations and conclusions of my own. Much has been said of the probable cause of the disease, but facts seem to be unknown; therefore, there is a great field of work before us. Obscure as the disease may seem to be, there must surely be some simple avenues of obtaining facts. We have read from writers on the subject that it is not a new disease, that it is probably 200 years old. We have only recognized it in south-eastern Kentucky within the last three years, but I believe it has been in this section to some extent for probably twenty years or more. Last spring and summer we had a large number of cases, but we also had a lot of pellagra-phobia.

In my experience with this malady since its appearance was recognized in the territory mentioned, I have not worked on any particular theory, or confined myself to any

special line or method of treatment; but rather have taken notice of all the theories and discontented myself by trying to find some new line of thought. Pellagra, I believe is not confined to any special sections of the State, but is present in some degree in all sections of Kentucky. I have seen some very typical cases in the western part of the State. But since the counties of Whitley, Knox, Laurel and Bell seem to be the site of the greatest development of this strange malady, and being myself located in the center of this territory, it might be presumed that my opportunities for study have been very good; but in the absence of facilities for giving the patients guarded attention in the way of diet, baths, etc., it has been a serious matter in my experience, to make it possible to do the question justice, and at the same time give proper attention to my general practice, from which I must look for my income. I do not recall having received but two small fees for services rendered pellagrous patients. I would be almost ashamed to take a bill if it were tendered me, for as a rule they are too poor to pay a bill.

The cases as a rule are very much scattered among the rough sections of the hills and mountains in places very difficult of access with reasonable convenience. The larger per cent. of pellagrins are very poor, unable to buy the necessary medicines and food stuffs, to say nothing of clothing, etc. May and June seem to be the most favorable time of serious developments. The disease has become so very prevalent, that the inhabitants have become very serious in their inquiries for some knowledge of prevention and treatment, and because of the honesty and frankness of the good men of the medical profession, admitting that the best known treatment is at most uncertain, and that no facts are known, a large number have through ignorance fallen into the hands of quacks, or a better term would be, robbers. A number of pitiful patients are possessed with a great deal of self-consciousness, and because of false rumors and the influence of evil persons, in the disguise of friends, are difficult of approach.

Therefore, the one serious question which confronts us is how to combat what seems to be the leading causative factors, ignorance, indifference to sanitary precautions, poverty, and various sins and vices. It moves me to see in my rounds the poor pitiful patients, especially in the case of children. It is appalling, not to say tragical. This thought leads me to mention malnutrition as an etiological factor and theory, though I believe a discarded theory, I believe worthy of the most careful consideration. The pellagrins and their associates are, as a rule, a class who select their food with little thought or knowledge

*Read before the Muldraugh Hill Medical Society.

of their food value. And a proper variety can not be had. These facts associated with the habit of eating and overeating cheap candies and other trash, and that between meals and sometimes taking the place of a meal, leads us to wonder that they are not more afflicted.

It is very common, even in the rural sections, to find families over-crowded in close rooms or huts. Infrequent bathing, irregular habits, eating of wild greens carelessly gathered, and of unripe fruits and drinking of surface water, etc., is to be remembered. In many cases the food is very poorly cooked and unattractively served, or rather not served at all, but fed to the poor little hungry children. We sometimes find housewives who do not empty their coffee pots of the old coffee, but sit it on the back of the stove to soak and simmer; day after day pouring off the black poisoned stuff for John or Jim to drink. This is not because the women are lazy, they are untaught and unthoughtful, following habits learned from their mothers and grand-mothers.

In visiting schools it so common to see school children tired and worn with an unattractive look because of malnutrition and disease. In this matter it seems that there could be no greater work for the Womans' Clubs and the churches than to give a part of their time to educating the well-meaning mothers in cooking and serving of food, for in so many instances these uninformed wives and mothers are pure at heart and virtuous, and are only too glad to be taught better modes of living. Right here I want to digress to say that in Corbin we have one of the most zealous and active Womans' Clubs in the State.

Since many investigators are working seriously on the question of the cause of pellagra we await anxiously some solution of the problem. I can not conclude that the disease is hereditary, or that it is contagious. It being endemic in character as has been noticed, would lead us to believe that it is toxico-infections, or due to some specific infection by bacteria or parasite. I believe the corn poison theory to be the least likely cause of any yet advanced, though it is certainly worthy of study. But in the meantime I occasionally take my corn bread as I have always done. But even if this theory were disproved altogether, I would warn the public to eat bread and syrup only from sound well cured corn. Dr. Saubon presents some strong points in his view of the sand-fly theory, but I am very skeptical about this theory, as I do not believe that the sand-fly really exists in this particular endemic center. Just here I desire to state that Prof. Garman, head of the State Agricultural Experiment Station, deserves great credit for the preliminary study which

he has made in south-eastern Kentucky working on the Saubon theory. All who have not done so should get a copy of his Bulletin No. 159 on this subject.

I quote an argument on this theory presented by some one as follows: "The season of the recurrence of pellagra coincides with the appearance of the full-fledged sand-fly, even to the extent that if the spring is early or late in appearing, the pellagra cases are early or late in their appearance." And again I quote, "In non-pellagrous districts the disease never spreads to others with the advent of a pellagrin from a pellagrous district." In the first instance I see little argument as the appearance of many things are governed by the season. And in the latter argument, I do not believe the statement can well be proven as correct.

We await further investigations this spring by Prof. Garman, which he has assured me he will do, covering the territory thoroughly.

Also during the fall of 1911 Dr. R. M. Grimm, of the Public Health and Marine Hospital Service worked our section very thoroughly gathering important data which in a reprint from the Lancet-Clinic can be had by any one by writing Dr. Grimm, at Savannah, Ga.

The only attempt to prove or disprove the simuliin or sand-fly theory so far as I know is being undertaken by Prof. Hunter of the University of Kansas, (see *Jour. A. M. A.* February 24, 1912). My observation has been that in many cases of pellagra there is an associated organic disease, and in most all cases a previous history of a "run-down" condition with the general system below par.

We owe it to ourselves to search for facts and in the meantime to impress upon the public the serious importance of better sanitary conditions. I believe that we as doctors, licensed by the State, owe it to the State to demand of the people in our territories cleaner methods of living.

SYMPTOMS.

As best I can observe in the cases I have seen, the first symptom is a feeling of distress with wanderings of the mind, a sharp development of temper and a sense of constriction; about the same time diarrhoea appears, followed in four to six days with a hyperemia or "sun-burn" on the back of the hands. Sometimes white spots scarcely noticeable occur on the hands just before the redness. The same condition of hyperemia may soon appear on the neck and the feet and the mouth usually becomes sore early, giving rise to pyralism later in the case; the patient becoming very nervous and irritable. Neuritis has been mentioned as a symptom. I

have never encountered it. I have seen only two cases with marked gastric disturbances. One case, an old man, presented a very severe congestion of the lungs, and almost complete loss of mind. I saw him in the last stages of the disease, a short time before death occurred. The characteristic skin lesions were prominent on hands, feet and face. I am not sure that he was not also tuberculous.

I notice that Dr. Hurty, Health Commissioner of Indiana, associates pellagra and hook-worm as one and the same disease. This from a man like Dr. Hurty comes as a surprise to me. Most assuredly he is wrong. I have seen and treated a number of cases of hook-worm, and fail to see but little similarity of symptoms. I have had typical cases of pellagra examined bacteriologically for the parasites with negative results. However, I admit the two diseases are sometimes associated together. I have seen such cases. I have noticed that a stoppage in the voice and sometimes stuttering are present in pellagrins. One can not but notice the peculiar symmetrical condition of the skin lesions. Many cases become demented early. A sore mouth is most always present and is a splendid diagnostic point in making an early diagnosis.

An interesting case treated by Dr. Sullivan was a woman, age 35; disease developed early in spring of 1911; had the diarrhoea; some mental symptoms; marked skin lesions on hands and neck; red swollen tongue. At the time the doctor saw her, she was nursing a five months' old baby which was nursed throughout the period, showing no sign of the disease itself. Both are now enjoying perfect health, apparently.

TREATMENT.

I will dwell very little on treatment as my experience has not been such as would be of much interest. Arsenite of copper, Fowler's solution or arsenic and dilute phosphoric acid have been used with good results. In the absence of any known specific, I do not recall to have treated any two cases alike. I have treated them as we say, symptomatically. Several cases in our territory have apparently gotten well, while some have died. I have seen two cases of the typhoidal type, both died. I read good reports from the use of soamin and salvarsan, and I note that "606" is being used with some satisfactory results. I have experienced little difficulty in controlling the skin lesions, if seen reasonably early. I use zinc and calamine in lanolin, or the simple oxide zinc ointment with a little balsam of peru is fine. Creosote in olive oil makes a nice lotion. In the more advanced conditions I have used aristol powder in the oxide ointment as a base with splendid results. I would not burden you with case reports, as

they would be of little value. I have treated some cases that have to all appearances gotten entirely well, and they insist on believing that I cured them, but I do not believe it. I have seen three cases that have apparently gotten well without any treatment at all. I do not believe that we are justified in using "606" until we know more of the etiology of the disease.

One doctor said to me "What are we going to do while this etiological work is going on. The quacks are reaping a harvest. Should we not tell the public that we have a specific and try to hold their confidence till we can arrive at some facts in the matter?" I say no, of course, but I admit that we should be active in some way to protect the public. In my own county a quack who is so illiterate that he spells pellagra with one "l" and in his circulars states that "Dr. P-e-r-r-y" was successful over Dr. Cook in his discovery of the Pole, and why question the discovery which he himself has made.

In conclusion I desire to thank the society for the invitation and for the privilege of presenting this essay.

PELLAGRA.*

By S. B. SNYDER, Jellico, Tenn.

For more than 200 years the etiology of pellagra has been a subject of serious inquiry. This problem, formerly an Old World question, now concerns us and it still awaits solution. It is now found in one-half the States of the Union and is quite prevalent in this locality.

The causation of pellagra is purely conjectural. An immense amount of work has been done by worthy investigators, but as yet its real cause is unknown.

The solution of this problem has been, at various times, proclaimed, but subsequent investigation has failed to furnish corroborative material.

Three theories have been advanced as to the cause of the disease: (1) the zoistic theory, based on the work of Ballardino in 1845, giving corn poison, due to the excessive use of corn products as the cause. This theory has been for years, and is now, most ably maintained by Prof. Lombroso of Turin, Italy.

(2) The cotton-seed products poison theory of Mizell, who argues that the advent of pellagra is due to excessive use of cotton-seed oil.

(3) The sand-fly theory of Sambon. The first two rest on the theory of malnutrition, the last on the action of a parasite. This is the theory that is likely to be finally accepted. Confirmation of this theory seems to be

*Read before the Whitley County Medical Society.

nearer every year since its first announcement two years ago.

Investigation shows a much wider distribution of simuliid or sand-fly than was at first believed. The facts on which this theory rests may be summarized as follows:

(1) The endemic centers of pellagra in Italy have remained the same since the disease was first discovered.

(2) The season of recurrence of pellagra coincides with the season of the full-fledged sand-fly. If the spring is early or late, making the appearance of the sand-fly early or late, pellagra cases are correspondingly early or late.

(3) In centers of pellagra infection whole families are attacked at times simultaneously.

(4) In non-pellagrous districts the disease never spreads to others with the advent of a pellagrin from a pellagrous district.

(5) If a family move from a pellagrous to a non-pellagrous district, the children born in the pellagrous district become pellagrins, but children born after removal never develop the disease.

(6) The disease is not hereditary, though very young infants may become infected, especially if taken to the fields where the mother works during the sand-fly season.

(7) Pellagra is not contagious, but is transmitted to each individual by an infected sand-fly, just as yellow fever and malaria are transmitted by mosquitoes.

THE DIAGNOSIS OF PELLAGRA IN PRONOUNCED CASES.

Having the pellagra triad of cutaneous, gastro-intestinal and nervous phenomena presents no difficulty, but cases are not uncommon in which the diagnosis is involved in much doubt. Outside of the erythema, there is no distinctive lesion of the disease, hence the diagnosis must depend on the "lights and shadows" of the clinical picture.

Early diagnosis is of much importance. The most important medical problem now occupying the pellagologic field is, without doubt, that of establishing an early diagnosis. Without this it is impossible to arrest or ameliorate the harmful effects of pellagra which seem fatally inevitable. Such a diagnosis too frequently involves many doubts and difficulties. Diagnosis necessarily is often tentative and treatment begun accordingly.

History of the case usually elicits mild mental disturbances such as dyspepsia, change in appetite, thirst or diarrhoea or constipation in the beginning. Diarrhoea is one of the most universally constant symptoms, and stools are often involuntary. Vertigo, insomnia, with headache, burning in the mouth, oesophagus and stomach sometimes hands and

feet. Pyrosis is a very constant symptom. Lombroso says, "Pyrosis is never absent."

Formication or a sensation of hands around the body sometimes precede the eruption.

General malaise, with muscular weakness, especially of the lower extremities, loss of weight, lowered physical, nervous and mental vigor are suggestive, but not peculiar to this condition.

The importance of an early diagnosis has led to a search for some characteristic blood or serum reaction, as the Widal reaction for typhoid, but has so far proved unreliable. The skin lesion from which the diagnosis is made, is said to be the most prominent and least important symptom of the disease. It is still a debated question whether we can have pellagra without the skin lesion (pellagra sine pellegra). Most observers give the cutaneous lesions the same diagnostic value as those of scarlatina, measles, variola. The characteristic symptom is a dermatitis, an erythema on the hands, face or feet—parts exposed to the sun. The distinguishing character of the eruption is its perfect symmetry, if it extends to one elbow, it is as sure to extend to the other, if it occurs on one foot, it develops at the same time on the other. The eruption may be either moist or dry—severe cases being moist and extending deeper.

After a variable time the eruption desquamates, leaving the surface soft, velvety and glistening, quite a contrast to the dirty, unwashed appearance of a few weeks before. The erythema soon reappears and follows the same course as before. This may occur several times during the summer. As a result of these repeated inflammations, the skin becomes hard and wrinkled, frequently deep fissures occur, especially on the fingers. Portions of the body subjected to pressure by the clothing show the eruption in some form.

The eruption begins in early spring and lasts until July, August or September, then disappears, to make its relapse in the spring—sometimes a relapse occurs in October.

The crowning characteristic of the eruption is its symmetry and color. After the pigmentation has been expoliated, a dirty, motley fringe remains, showing the extent of the dermatitis; in the colored race the pigmentation is increased, having the appearance of having had soot rubbed into the skin, but persistent efforts with soap and water fail to remove the dirty appearance.

The first symptom for which the physician is consulted in mild cases is a "sunburn" that refuses to yield to cold cream, or other household remedies.

In the treatment much is to be desired. Every practitioner feels that he has a treatment that does good—at times. Treatment of

pellagra is becoming the rich field of the itinerant, swindling quack. In pellagra, as in all incurable diseases, when honest, competent, conscientious physicians give an unfavorable prognosis, the faker proceeds to fleece the poor victim. In this county a physician who is supposed to be regular is associated with a charlatan, advertising and peddling a "sure cure" for pellagra. The stuff is worthless for pellagra or for anything else for that matter.

The treatment must, of necessity, be largely symptomatic, sulphid of calcium has many advocates, given in 1-2 to 2 grains, four times daily is said to be specific. (Mizell) Arsenic has its advocates, given as Fowler's solution up to physiological effect. I have used this with good results. Injection of salvarsan has been rather disappointing in the hands of competent observers.

Transfusion of blood from a recovered case has been very successful in many cases.

Until the true cause has been found, the treatment must be more or less unsatisfactory.

SERUM AND VACCINE THERAPY.*

By O. P. CHAPMAN, Port Royal.

In the beginning of this brief paper I want to say that if the length of this discussion depended on the writers' personal experience the paper would be very brief indeed.

That certain diseases are communicable and that in many such diseases one attack renders the individual immune to subsequent attacks, has been known since the dawn of medicine; but it was left to our generation, through the development of the science of bacteriology, to work out the causes of disease and the nature of the immunizing mechanism, thus teaching us how to take advantage of Nature's immunizing process and to apply it as a prophylactic and curative agent.

Pathologic bacteria whose vitality has been destroyed by heat and suspended in physiological salt solution are called bacterins or bacterial vaccines.

Serums are the liquid portions or serum of the blood of animals that have been treated with gradually increased doses of bacterial toxins or attenuated or killed cultures of the organisms themselves.

The results of the bacterial growth are called toxins.

Behring was the first to bring out this immunizing process as a therapeutic measure by the application of antidiphtheritic toxins in the treatment of diphtheria.

The results of his experiments were so striking that it was at once supposed that serums

could be produced that would have the same brilliant effect on all other infectious diseases, in this we have been doomed to disappointment for many of the other micro-organisms when so treated do not respond like the diphtheria bacillus.

Various theories have been advanced to explain how the immunizing bodies are formed in the human body; Klebs and Pasteur claim that certain substances necessary as food for the bacteria, when exhausted immunity necessarily follows.

Chanceaux says that products in the body which protect the body tissues from further invasion by the particular parasite.

Metchnikoff holds that immunity was obtained by the ability of the white blood cells of certain organs of the body to engulf and destroy the invading bacterium.

Fodor believes the normal body fluids and especially the blood, contain substances that are able to destroy bacteria.

Chamberlain, Foa, Renome, Roux and others think that body tissues are chemically changed in immunization.

However, the "side chain" theory of Ehrlich, which he advanced in 1897 is the one generally accepted as explaining the immunity produced by the antitoxins, he supposed that the complicated proteid molecules in living matter contains many groups whose function it is to attract food substances into the molecules, when such a group combines with the toxine, the combination being injurious to the proteid molecule, is thrown off, similar groups produced to supply the deficiency are likewise thrown off, the molecule in this way acquires the power of group production, these groups being produced in excess of its demand, some of the extra groups are contained in the blood stream and the serum containing them is called antitoxine.

Their affinity for toxines and their power to render toxines harmless is the secret of their ever increasing use in medicine.

Wright concludes from the investigations that the blood serum contains a substance which has a sensitizing effect on the invading organisms and that this substance is naturally increased during the immunizing.

The bacteriologic substance has been termed an opsonin. Wright noting the phagocytic power of the blood as demonstrated in the incubated test tube was led to make many more extended investigations as to the opsonic power of the blood of man under various conditions.

By an extended process, which we have not time nor space to take up in this paper, he arrived at a measurement and calls it the "opsonic index", he also found by taking the opsonic index at short intervals, that when a sufficient number of previously sterilized path-

*Read before the Henry County Medical Society.

ogenic bacteria are injected under the skin, the immunizing power of the blood is aroused producing more opsonins and likewise resulting in an increased phagocytosis.

Repeated opsonic readings, furthermore, showed that the increased destroying power resulting from a single dose of vaccine would continue from five to ten days or more and that if the inoculations are repeated at proper intervals this immunity would become permanent.

What is said of vaccines may also be said of serums in a great measure, by some it is claimed that the serums are more useful in acute general infections, while vaccines are giving better results in localized and semi-localized infections.

We are all more or less familiar with the splendid results in the use of smallpox vaccine and antidiphtheria toxine but in the use of tetanus antitoxine, antimeningococcus, antipneumococcus, antistreptococcus serums and tuberculin some of us have had but little personal experience.

These and some other products have given satisfactory results in the hands of many doctors.

Vaccines and serums are not infallible, they have limitations and while they yielded brilliant results in selected cases they should still be regarded as auxiliary means of treating infectious diseases and as supplementary to other resources of up-to-date surgery and medicine.

VACCINE AND SERUM THERAPY.*

By S. D. TAYLOR, Beaver Dam.

Vaccine and serum therapy, defined in a general sense means the introduction into the system of killed pathogenic organisms or their products; for the prevention and cure of infectious diseases produced by like organisms; they are also used for diagnostic reactionary evidence of infectious diseases an example of which is seen in tuberculosis with the several tests made with the tubercular vaccine.

Vaccines and serums are most generally prepared in the laboratory for immediate use, the so-called stock products from animals and the human subject that are immune or convalescent from the infectious virulent bacteria and their products; they are also obtained from other substances and cultures from other media. These differ from the autogenous vaccines which are prepared from cultures of bacteria obtained from the patient direct and administered back to him for immunizing purposes.

These products are prepared under strict aseptic conditions carefully standardized and

tested as to purity and efficiency; so that definite doses may be administered and certain therapeutic effects may be expected under proper conditions in a given case.

While this is a comparatively new field in therapeutics, the principles involved dates back many centuries, when it was known that an attack of certain infectious diseases conferred a partial or complete immunity to a recurring attack of those diseases.

Inspired by this knowledge Jenner, in 1798, was led to conduct his experiments upon cases of small-pox which resulted in the discovery of an artificial immunity to that disease by producing the variola vaccine, at which time he also published a report of his investigations entitled "An inquiry into the cause and effect of Variola Vaccine."

Koch, in 1890, was the first to attempt to cure an infectious malady by a specific, viz.: of tuberculosis by means of tuberculin, since then scientific research and clinical study has done much to elucidate this phase of medicine and establish it upon a scientific basis.

A new era has dawned in medical therapeutics, and the profession is now able to offer hope to those suffering with infectious diseases that only a few years since would have been doomed to life-long suffering or an untimely death.

"The principles underlying this treatment is based upon the reaction between the invading virulent bacteria and its secretory products; the toxins upon one hand; and the body defenses upon the other."

For an infection to occur, the bacteria must gain entrance into the body through some avenue adapted to their cultural requirements; which are most generally found in the skin and mucous surfaces; at points where the body defenses are the weakest.

However, not all pathogenic bacteria that enters the body gain a foothold and produce an infection; since the tissues, fluids and cells of the body, if healthy, have at their disposal certain general elements or body defenses, that will overcome the invading foe, provided the number is not too great, or the bacteria too virulent in character.

Bacteria after gaining entrance into the body are either localized by the cell protectors, and produce their effects by the toxins which they secrete and which are absorbed by the lymphatics; or the bacteria get directly into the lymphatic system and blood current and produce a bacteremia.

The toxins of bacteria are the secretory products of the bacteria which pass in to the culture media during the life of the bacteria. The bacteria which secrete toxin in the media in greatest abundance are the most virulent; examples of which are seen in the tetanus and diphtheria bacilli. There is another class of

*Read before the Ohio County Medical Society.

bacteria which give up their toxins to the culture media very sparingly, in this case the toxins remain attached to the bacterial body, such poisons when separated from the bacteria after death of the bacilli are termed endotoxins; and the greater number of bacteria seem to act by means of these endotoxins; examples of this class are seen in the typhoid bacilli and the cholera vibrio.

Bacterial bodies after removal of their toxins and endotoxins have a certain proteid residue remaining; called bacterial protein, which though without special toxic properties is capable by its chemical effects on the white blood cells to produce pus formation.

The elements of the body defense or the natural immunity to infectious disease may be considered under the following heads: 1st. The protection afforded by the body surfaces; the skin and mucous membranes, which owing to their structure and peculiar secretions, offer strong opposition to the invading microorganism. 2nd. The protective nature of inflammatory products, when the pathogenic bacteria enters the tissues of the body an inflammatory action is immediately begun; when mechanically through the formation of new connective tissue, and a dense accumulation of leucocytes and fibrin around the focus of infection the invaders are walled off from the surrounding health structures. 3rd. Through the antibacterial and antitoxic action of the lymph and serum, which contains natural antitoxins and in addition they are said to lessen the toxicity of the poison by diluting them and eliminating them from the body. 4th. By the phagocytes, which ingest and destroy the offending bacteria, while at the same time they may absorb bacterial poisons and in some way destroy their toxicity. 5th. By the opsonins, which are produced by subcutaneous and muscular activity, and which in some manner increase the power of phagocytes to destroy the bacteria.

A bacterial vaccine or bacterin is a pathogenic bacteria which has been destroyed by heat and held in suspension in a normal salt solution and kept by a preservative. The effect when administered is to increase the destructive power of the patient's leucocytes against the specific virulent bacteria. In other words, the injection of a dose of bacterial vaccine stimulates the patient's body to manufacture a greater supply of antibodies and thus enables him to resist disease-invading germs; thus conferring an active immunity to the specific disease. Their therapeutic value lies in preventing the invading pathogenic bacteria from gaining a foot-hold on the tissues of the body and in localizing them after they have gained an entrance; for example in the early stages of puerperal sepsis before general sepsis has taken place, strep-

tococcus vaccine is indicated. They are indicated in all local affections; as the gonococcus vaccine in gonorrhoea; and the staphylococcus vaccines in the treatment of acne, syecosis, furuncles and carbuncles.
